HYATT WOUND ROLLER SPLIT RACE BEARINGS

These bearings are designed to operate directly upon the surface of commercial fractional size shafting. They are of the separable type, being composed of a roller assembly and an outer race. The outer race assembles into the housing bore and serves as the outer operating surface for the rollers.

Bearings of this type have a long record of successful performance in industrial trucks, casters, conveyors, mine cars and similar types of equipment where bearing space is not at a premium and speeds do not exceed 1000 rpm.

Roller Assembly

The roller assembly consists of rollers and a cage. The rollers are spaced and held together by the cage.

There are two types of roller assembly: the alternate-bar-and-roller type, and the full-complement type—both shown in cross section above. In the former, the rollers and bars alternate, the rollers being assembled on projecting knobs punched in the end ring. Bearings of this type compose the 18,000 and 49,000 series.

In the full-complement type bearing, the bars pass through the hollow rollers. This permits a "full-complement" of rollers, thereby providing the maximum number of rollers that can be assembled in a given pitch circle. These bearings form the 40,000 series.

Rollers

The distinctive Hyatt rollers are hollow cylinders, formed by helically winding strips of alloy steel, which are then cut to length, heat treated and ground to close limits. This treatment results in high resistance to shocks, abrasion and fatigue.

The rollers are wound with both right hand and left hand turns and are assembled alternately in the bearing. This arrangement has the effect of sweeping the lubricant back and forth across the race surface.

Cage

The rollers are kept in proper alignment and uniformly spaced by the cage or retainer. This consists of two pressed steel end rings, rigidly

held in parallel and concentric position by round steel spacing bars. The ends of the bars are riveted in countersunk holes in the end rings.

Outer Race

The split outer race is made of a strip of specially finished medium carbon steel, rolled in cylindrical form. The joint is in the form of an obtuse angle so that the rollers pass over it without shock or noise. Before insertion in the housing bore, the split race will be found to have a slight outward spring which results in opening the joint somewhat. By pressing into the bore, the race is brought to true cylindrical form, the joint is closed to its proper width and the spring of the race practically eliminates any turning or creep in the bore.

ALL SIZES LISTED ARE IN PRODUCTION

BEARING SELECTION

Select bearings which will fulfill the load requirements of the application at the operating speed to be encountered from the tables on pages 4 and 5. The load ratings are based upon a shaft hardness of 169 Brinell, and upon a revolving shaft. When other conditions exist, and when temperature or service requirements may be severe, modifying factors must be used . . .

Shaft Hardness Factor

For shaft hardnesses other than 169 Brinell, a Hardness Factor corresponding to the shaft hardness is taken from the chart at right. This factor will depend upon whether the shaft is stationary or rotating. In either case, the applied load is divided by the Hardness Factor in order to determine the required bearing load rating.

Temperature Factor

Temperatures up to approximately 350°F, have little or no effect upon the hardness of Hyatt Wound Roller Bearing parts. Above this, the temper of the material becomes affected with consequent decrease in hardness and in strength. It is therefore necessary to apply modifying factors to the bearing ratings, when temperatures above 350°F are encountered. The modifying factors are shown in the chart at right.

Service Factor

The Service Factor is intended to compensate for the type of load—whether continuous or variable, the presence of shocks or overloads, the degree to which the

bearing is protected from foreign matter, and the attention which it will receive. It is not possible to generalize service conditions into definite factors, so the accompanying table can serve only as a guide. When selecting a bearing size, the value of the applied load should be divided by the service factor.

Required Bearing Load Rating

The bearing load rating required for satisfactory bearing performance, is found by means of the following equation:

$$R = \frac{L}{A \times B \times C}$$

where

- R = Required bearing load rating
- L = Load imposed on bearing
- A = Shaft hardness factor
- B = Temperature factor
- C = Service Factor

SERVICE FACTORS

Type of Equipment	Service Factor
Agricultural Implements	1.00 to 1.50
Belt Conveyors:	
Idlers with revolving shafts.....	.35 to .50
Idlers with stationary shafts.....	.25 to .35

INSTRUCTIONS FOR MOUNTING

Retainment of Bearing Parts in Correct Operating Position

Provision must be made in the housing design to retain the bearing in its proper position since both rollers and races are straight cylinders. This is done by providing a flat smooth surface, on both sides of the bearing, which extends sufficiently to cover approximately two-thirds of the roller diameter.

When the retaining surfaces project inward from the outer race or housing bore, the retainment is said to be of the "housing or outer race type." When the retaining surfaces project outward from the shaft the retainment is said to be of the "shaft or inner race type." The housing type retainment is simpler and more economical, but the design of adjacent parts usually determines which type should be adopted.

Care should be exercised to guard against diagonal or cross retainment where the retaining surface on one side is of the housing type and on the other side of the shaft type. With such incorrect retainment any considerable movement of the shaft, axially, will pinch the roller assembly between the two retainment surfaces and prevent the bearing from functioning properly. This is shown below.

Endwise Location of Shafts

The Hyatt Bearing, of itself, provides no means of taking end thrust, being designed for radial loads only. It is necessary, therefore, to provide some means out-

side the bearing itself to locate the shaft in its correct lengthwise position. Plain thrust surfaces, preferably steel against cast iron, are sufficient for most applications.

Wheel and Pulley Stability

When Hyatt bearings are mounted in a wheel or pulley hub, the question of lateral stability of the wheel or pulley frequently supersedes the ordinary consideration of load. The two new elements to be considered are the diameter of the pulley or wheel, and the width of the pulley face. If a single bearing is used in a loose pulley hub, it must be at least as wide as the pulley face, must be placed centrally with respect to the face, and must not be shorter than $1/3$ of the pulley diameter. A single bearing in a plain tread wheel or single flanged wheel must not be shorter than $1/3$ of the wheel diameter, and if this ratio is used with single flanged wheels, the center line of the bearing must coincide with the track gauge line. If the bearing is as long as $1/2$ the wheel diameter or longer, the center line of bearing must coincide with the center line of track.

When the observance of these rules requires the use of a bearing longer than those available, two bearings with a spacer between are substituted. If the spacer width is equal to or greater than the width of one of the bearings, the permissible diameter of the wheel or pulley may be five times the combined width of both bearings and spacer. The permissible width of pulley face is the sum of the widths of the two bearings plus the width of the spacer.

TYPES OF RETAINMENT

Housing or outer race type retainment

CORRECT

Shaft or inner race type retainment

CORRECT

Diagonal or cross retainment

INCORRECT

Lubrication and Sealing

End plates which locate the outer race and roller assembly, also serve as seals to prevent the escape of lubricant and the entry of dust or dirt. Some methods of holding the end plates in the housing are shown here, the particular type to be used depending upon the circumstances of the application.

Plates may be stamped or cast and turned to size. A clearance of from $\frac{1}{64}$ " to $\frac{1}{16}$ " should be provided around the shaft, depending on shaft size. Where loose washers or plates are used outside the housing, the diameter of such plates should be large enough to bear not only on the bearing retainment plate, but also on the housing itself.

POSITIONING OF END PLATES IN HOUSING

MORE THAN 3,500 SIZES....**

Hyatt Spherangular Roller Bearings

An angular contact, self-aligning bearing designed to sustain both radial and thrust loads. The operating surface of the outer race has a spherical contour, and the rollers and races make angular contact, insuring ideal distribution of load on roller and race surfaces even under conditions of misalignment or shaft deflection.

All radial and thrust loads are distributed on the curved roller paths over large areas of contact with the greatest load concentrated at the center or major diameter of the rollers. The absence of race shoulders avoids destructive pressures on roller ends.

Hyatt 90,000 Series Bearings

HP-90,000 series are two part bearings with split outer races and solid roller assemblies. They may operate directly upon the unmachined surface of cold rolled shafting. Maximum load rating may be realized with shafts of 400 Brinell hardness.

S-90,000 series are two part bearings composed of solid cylindrical, hardened and ground outer races and solid roller assemblies. Suitable for applications requiring higher load rating and accuracy than the HP-90,000 series. Commonly applied to ground shafts of 55C Rockwell hardness.

Roller assemblies only of both series are also available. Recommended where both operating surfaces may be hardened to 55C Rockwell minimum hardness, and ground to close limits.

Hyatt Industrial Inch Series Bearings

Designed for slow moving, heavily loaded machinery where, as in oil well or steel mill equipment, large diameter shafts are the rule. Available in fractional size bores for shafts from 4" diameter upwards.

Made up of three separable parts: outer race, roller assembly and inner race. Rollers are retained by a cage made up of bronze end rings held together and properly spaced by steel bars.

Hy-Load Solid Roller Bearings

High capacity cylindrical roller bearings made in three dimensional series, wide and narrow widths, to standard AFBMA dimensions. There are ten major types—for radial loads, or light or intermittent thrust loads. Of the ten types, two have non-separable component parts, four have separable inner races, four have separable outer races, thus permitting flexibility in machine design and assembly procedures. Separable race can

be omitted, and rollers operated directly on the machine surfaces, in instances where shaft or housing bore is of suitable hardness and finish.

Wound Roller Bearings With Solid Outer Races

Contains the distinctive Hyatt wound roller, formed by helically winding strips of alloy steel, heat treating and grinding to close limits. The races are straight cylinders of alloy steel. This combination results in a bearing possessing maximum resistance to shock, abrasion and fatigue effects, making it particularly suitable for the severest kinds of service.

Either or both races may be omitted by providing operating surfaces of sufficient hardness and suitable finish.

Hyatt Type J Railroad Bearings

Consist of cylindrical races and solid rollers operating in one-piece bronze separators. Rollers are formed from alloy bar stock and races from alloy steel forgings, properly heat-treated and ground to close limits.

The inner race is shrunk on the journal portion of the axle, and becomes an integral part of the axle. Wheel work may be done without disturbing the race.

There are two roller assemblies to each journal. The roller separators are bronze castings of wear-resisting alloy composition, and are centered on the inner race to insure concentric operation at high speeds.

FOR EVERY APPLICATION.....**

World-Wide Sales-Engineering NetworkAt Your Disposal

FOR MORE THAN 50 YEARS, Hyatt sales engineers have been literally "walking encyclopedias" of bearing information for manufacturers of machines and equipment, and their designers.

During this time these men have accumulated a tremendous fund of technical knowledge of the application of Hyatt Roller Bearings. In this vast reservoir of experience, there may already be solutions to mechanical obstacles that you encounter in the products you are developing or improving today. Even if there has not been a problem to parallel yours, they are ready to help you find the right answer . . . one that will contribute to better design and better operation.

Consultation with Hyatt engineers is easy to arrange and involves no obligation.
