ENGINEERING

INTRODUCTION

Timken is a leader in the advancement of bearing technology. Expert craftsmanship, well-equipped production facilities, and a continuing investment in technology programs ensure that our products are synonymous with quality and reliability. Today, our plants manufacture thousands of bearing types and sizes to handle a wide range of application requirements.

Anti-friction bearings inherently manage broad ranges of speed and many combinations of radial and thrust loads. Other important environmental conditions, such as low and high temperature, dust and dirt, moisture, and unusual mounting conditions, affect bearing operation.

This engineering section is not intended to be comprehensive, but does serve as a useful guideline in bearing selection. Where more complex bearing applications are involved, your Timken representative should be consulted. The following topics are covered within this section:

- Bearing types
- Cages
- Internal clearances
- Tolerances
- Shaft and housing fits and shoulders
- Load ratings and life calculations
- Lubrication
- Materials
- Limiting speeds
- Duplex bearings and preloading

BEARING SELECTION PROCESS

Bearing selection is a process for evaluating the suitability of bearings for specific industrial applications. The quality of the information available to make these selections will play a major role in determining the success of the bearing choice.

The first step in bearing selection is identifying the proper roller element type, whether it is a ball, needle, cylindrical, spherical or tapered roller bearing. Each roller bearing type has advantages and disadvantages that are specific to each design and will affect such things as the loads and speeds that the bearing can sustain in the application.

Next, assess the size constraints of the bearing envelope or available space. This is done by considering the minimum shaft diameter, maximum housing bore and available width within the application for the bearing. After the bearing envelope is defined, search the catalog for bearings with bores, outer diameters and widths that will fit within the bearing envelope. There may be several bearings with different load-carrying capacities available that fit within the envelope.

Determine which of these bearings will give the desired life in the application by performing a bearing life analysis for each bearing. The following sections in this catalog give a detailed explanation of how to perform bearing life analysis.

Once you have chosen the right bearing to handle the load requirements of your application, and the design options are chosen, the bearing selection is completed. These options include such features as cage type, cylindrical roller bearing flange arrangements, radial internal clearance or setting, precision level and lubrication. These options are selected based on the application's speed, temperature, mounting and loading conditions, and will enable you to achieve optimum bearing performance and life.

For a closer look, your Timken representative can provide you with expert computer analysis to give you the most detailed information for your bearing application.

A | BEARING TYPES AND CAGES

BEARING TYPES
RADIAL BALL BEARINGS

The basic types of Timken ball bearings are shown here. They are the non-filling slot or Conrad, which is identified by the suffix K and the filling slot designated by the suffix W.

The non-filling slot or Conrad bearing has uninterrupted raceway shoulders and is capable of supporting radial, thrust or combined loads. The filling slot type, which is assembled with more balls than a K-Type of the same size, has a greater capacity than the K-Type, but has limited thrust capacity due to the filling slots in the raceway shoulders.

Both K and W can be mounted with or without locknuts and either fixed or floating in their housings as illustrated here.

Suffix K   Suffix W   Fixed Mounting   Floating Mounting
ANGULAR CONTACT BALL BEARINGS

Single-Row Type

Single-row, angular contact ball bearings are designed for combination loading with high thrust capacity in one direction, and are suggested for applications where the magnitude of the thrust component is high enough to preclude the use of radial type ball bearings. They are dimensionally interchangeable with single-row radial bearings of corresponding sizes.

The angular contact ball bearing has a relatively large contact angle, high race depths, and a maximum complement of balls assembled through a counterbore in the outer ring. These features provide bearings with significantly more thrust capacity than radial bearings of the same size.

Angular contact bearings are used in such applications as gear reducers, pumps, worm drives, vertical shafts and machine tool spindles, where they are frequently mounted in various duplex arrangements as described in the duplex section.

Double-Row Type

Double-row, angular contact ball bearings are used effectively where heavy radial, thrust or combined loads demand axial rigidity of the shaft. This type is similar to a duplex pair of single-row bearings by virtue of its two rows of balls and angular-contact construction, which provide greater axial and radial rigidity than can be obtained by using a single-row radial bearing.

With the exception of small sizes, double-row ball bearings are made in the filling slot construction, and therefore, do not have as much thrust capacity as equivalent size single-row, angular contact bearings mounted in duplex pairs. Fixed and floating mountings of double-row bearings are shown. Smaller sizes are supplied with polymeric retainers.

Single-Row

Fixed Mounting   Floating Mounting

Typical Mountings for Double Row, Angular contact Ball Bearings
BEARING TYPES AND CAGES – *continued*
BALL BEARINGS WITH SNAP RINGS (WIRELOC)

Single-row radial bearings including those with seals or shields and open and shielded double-row types are available with snap rings, which provide a shoulder integral with the bearing, designed for mounting in through-bored housings. This feature is designated by adding the suffix "G" to the standard bearing number. Single shielded or sealed bearings with snap rings can be supplied with the snap ring on the same side or that opposite the shield or seal position.

These bearings are advantageous in automobile transmission design and in all applications where compactness is essential, or where it is difficult and costly to machine housing shoulders. The

snap ring provides an adequate shoulder for the bearings without a sacrifice in bearing capacity. The thrust capacity of the snap ring in shear is considerably above the thrust capacity of the bearing.

Typical designs illustrating how mounting simplification can be accomplished through the use of snap ring bearings are shown (below).
Typical Mounting For Snap Ring Bearing

SUPER PRECISION BALL BEARINGS

Every Timken Fafnir ball bearing manufactured is made to precision tolerances. The standard tolerances established by the Annular Bearing Engineers Committee (ABEC) are adhered to, and even the most liberal classification, ABEC 1 ensures a precision product by nature. Many applications in numerous types of machinery can be satisfactorily operated with ABEC 1 tolerance bearings.

However, for applications involving high speeds, extreme accuracy and rigidity in such equipment as high-grade machine tools, woodworking machines, gas turbines and sensitive precision instruments, a complete line of Timken Fafnir super precision ball bearings is manufactured to ABEC 7 and ABEC 9 tolerances.
Typical Application For Super Precision Bearing

A

BALL BEARINGS WITH LOCKING DEVICES

By virtue of their independent locking devices, these bearings are suitable for mounting on straight shafting (no shoulders, etc.). They are often supplied with spherical outer rings for self-alignment at mounting. Mounted alignment is usually required because these bearings are generally assembled into pillow blocks or flanged cartridges, or other housings bolted to pedestals or frames independent of each other.

Self-Locking (Eccentric) Collar

Timken invented the eccentric self-locking collar to facilitate mounting of wide inner ring bearings. The self-locking collar eliminates the need for locknuts, lockwashers, shoulders, sleeves and adapters.

The locking collar has a counterbored recess eccentric with the collar bore. This eccentric recess engages or mates with an eccentric cam end of the bearing inner ring when the bearing is assembled on the shaft.

The collar is engaged on the inner ring cam of the bearing. This assembly grips the shaft tightly with a positive binding action that increases with use. No adjustments of any kind are necessary. The collar setscrew provides supplementary locking.

Easiest of all to install, wide inner ring ball bearings with self-locking collars are available in various sizes. These bearings shown with various seal and inner ring width variations serve many purposes in farm and industrial applications.

RA-RR Series
Extended Inner Ring
with Locking Collar

Shroud-Seal KRRB Series
Wide Inner Ring
with Locking Collar

Setscrew Series Bearings

The GYA-RRB and the GY-KRRB series relubricatable and non-relubricatable bearings are extended inner ring and wide inner ring type bearings with specially designed setscrews to lock on shafting. Positive contact land-riding R-Seals provide protection against harmful contaminants and retain lubricant. Extended inner ring bearings are used when space is at a premium and overturning loads are not a problem. The new wide inner ring setscrew series is available when additional surface contact on the shaft is a requirement for added stability.
YA-RR Series

Concentric Collar

Using the concentric collar, the bearing is locked to the shaft by two setscrews, 120 degrees apart, tightened in the collar and passing through drilled holes in the inner ring. These units are suited for applications where space is limited and reversing shaft rotation is encountered.

GC-KRRB Series

NEEDLE ROLLER BEARINGS

Timken needle roller bearings are an economical alternative for applications requiring minimal space to carry a given load at a desired speed. Needle roller bearings can be an ideal choice because of their ability to handle a given level of speed and load capacity, yet have the smallest cross-section of all roller bearing types – and, at a very attractive price.

Timken offers both inch and metric nominal bearings in popular designs such as: drawn cups, radial caged needle rollers, machined ring, track rollers, thrust bearings, combined bearings, and drawn cup roller clutches. Most of these bearing types can be operated directly on a machined shaft of suitable quality, or with a matching inner ring where this requirement cannot be conventionally satisfied.

Radial Caged Needle Rollers

Timken Torrington needle roller and cage radial assemblies have a steel cage that provides both inward and outward retention for the needle rollers. The designs provide maximum cage strength consistent with the inherent high load ratings of needle roller bearings. Accurate guidance of the needle rollers by the cage bars allows for operation at high speeds. Needle roller and cage assemblies are manufactured with either one or two rows of needle rollers.

Drawn Cup Bearings

The outer ring in the form of a cup is accurately drawn, and no subsequent machining is performed to build the outer raceway. Drawn cup needle roller bearings are available in open ends or single, closed (to protect the shaft) end designs. They are also available with one or two integral seals. Other options include a single lubricating hole, and matching inner ring.

Heavy-Duty (Machined) Needle Roller Bearings

These bearings are available in a wide range of inch and metric sizes plus an array of design features including: integral seals, side flanges (or separate end washers), inner rings, oil holes, and single or double caged sets (or full complement) of rollers.

Track Rollers

Timken Torrington track rollers listed in this catalog have been designed with outer rings of large radial cross section to withstand heavy rolling and shock loads on track type or cam-controlled equipment. The outside diameters of the outer rings are either profiled or cylindrical. Profiled track rollers are designed to alleviate uneven bearing loading resulting from deflection, bending or misalignment in mounting. Stud-type track rollers are available with or without lip contact seals, or with shields. Yoke-type track rollers are designed for straddle mounting. Each yoke-type is available with either needle roller and cage radial assemblies, or with a single (or double) full complement row of cylindrical or needle rollers.

Thrust Bearings

Needle roller and cage thrust assemblies are available in a variety of inch or metric sizes. All types have very small cross-sections. If the back up surfaces cannot be used as raceways, hardened washers are available. Thrust bearings are available with needle rollers or heavier cylindrical rollers for high load carrying capacity.

Combined (Radial and Thrust) Bearings

Timken combined bearings consist of a radial bearing (needle roller bearing) and a thrust bearing (needle or other roller bearing). Some combined bearings are constructed similar to drawn cups, but with an added thrust bearing component. Like other needle bearings, these combined bearings can be matched with an optional inner ring or thrust washer as the opposing raceway.

Roller Clutches

Drawn cup roller clutches transmit torque between the shaft and housing in one direction and allow free overrun in the opposite direction. When transmitting torque, either the shaft or the housing can be the input member. Applications are generally described as indexing, backstopping or overrunning.

In many respects, construction is similar to that of drawn cup bearings, utilizing the same low profile radial section as drawn cup bearings. The precisely formed interior ramps provide surfaces against which the needle rollers wedge to positively lock the clutch with the shaft when rotated in the proper direction. These ramps formed during the operation of drawing the cup, are case hardened to assure long wear life. The incorporation of ramp forming into the cup drawing operation is a Timken manufacturing innovation that contributes much to the low cost of the unit.

A

BEARING TYPES AND CAGES – *continued*

NEEDLE ROLLER BEARING SELECTION

Because of the possible combinations of roller complement orientation, bearing cross-section thickness, and raceway construction, needle roller bearings should be given extra consideration for roller bearing applications selection. The table below should be used as a general guideline for the application of Timken needle roller bearings.

NEEDLE ROLLER BEARING CAPABILITY COMPARISON BASED ON SUITABLE OIL LUBRICATION

| Bearing Design Bearing Capability	Needle Roller Type Assembly	Drawn Cup & Cage Radial Bearing Caged	Drawn Cup Needle Roller Full Complement	Needle Roller Roller Bearing Inner Ring	Track Roller Bearing & Assembly	Needle Roller & Cage Thrust	Needle Rollers	Combination

RADIAL SPHERICAL ROLLER BEARINGS

The principle styles of radial spherical roller bearings are offered by Timken: CJ, YM, YMB, VCSJ and VCSM.

CJ   YM / YMB   Tapered Bore Bearing with Adapter Sleeve Assembly

YM bearings offer the greatest range of sizes in all series. They combine Timken design experience with proven performance in many industries.

All of the newer styles (CJ, YM and YMB) offer higher load ratings for longer life. CJ bearings include a stamped steel cage and are suitable for a broad range of general service applications. For extreme conditions of use, the YM and YMB style, with a machined brass cage, should be considered.

All styles are available in straight or tapered bores. Tapered bore bearings can be ordered by placing a "K" immediately after the numbers in the bearing description (e.g., 22311KYM).

Tapered bore bearings are available with adapter sleeve assemblies consisting of sleeve, locknut and washer. Adapter sleeve assemblies are designated SNW (e.g., SNW117).

Timken spherical roller bearings have been developed to accommodate radial and axial loads. The internal geometry allows the inner ring to accommodate misalignment. This capability is unique to spherical roller bearings allowing machine designers more tolerance and less restrictive assembly. Other data is listed.

Timken spherical roller bearings are available in ten dimensional series conforming to ISO and ANSI/ABMA standards. An illustration is presented below.

Optional features available with Timken spherical roller bearings:

W33 Lubrication Groove and Oil Holes

A lubrication groove and three oil holes are provided in the bearing outer ring. This eliminates the expense of machining a channel in the housing bore for introducing lubricant to the bearing. This design feature allows the lubricant to flow between the roller paths, through a single lubrication fitting. The lubricant moves laterally outward from the center of the bearing, reaching all contact surfaces and "flushing" the bearing. To order, add the suffix "W33" to the bearing number (e.g., 22216W33).

W22 Selected Outside Diameter Bearings

Bearings with selected outside diameters are required in some applications. Timken spherical roller bearings are available with reduced outside diameter tolerance. This allows a close control of the fit between the bearing and housing.

To specify this feature, add the suffix "W22" to the bearing number (e.g., 22216W22).

Additional features are available, consult your Timken representative for more information.

RADIAL CYLINDRICAL ROLLER BEARINGS
Standard Styles

A Timken cylindrical roller bearing consists of an inner and outer ring, a roller retaining cage, and a complement of controlled contour cylindrical rollers. Depending on the type of bearing, either the inner or the outer ring has two roller guiding ribs. The other ring is separable from the assembly and has one rib or none. The ring with two ribs axially locates the position of the roller assembly. The ground diameters of these ribs may be used to support the roller cage. One of the ribs may be used to carry light thrust loads when an opposing rib is provided.

The decision as to which ring should be double-ribbed is normally determined by considering assembly and mounting procedures in the application.

Types RU and RIU have double-ribbed outer and straight inner rings. Types RN and RIN have double-ribbed inner and straight outer rings. The use of either type at one position on a shaft is ideal for accommodating shaft expansion or contraction. The relative axial displacement of one ring to the other occurs with minimum friction while the bearing is rotating. These bearings may be used in two positions for shaft support if other means of axial location are provided.

SERIES
239   230   240   231   241   222   232   213   223   233

BEARING TYPES AND CAGES *– continued*
RIU, RU, NU	RIN, RN, N	RIJ, RJ, NJ	RIF, RF, NF	RIT, RT, NUP	RIP, RP, NP
Types RJ and RIJ have double-ribbed outer and single-ribbed inner rings. Types RF and RIF have double-ribbed inner and single-ribbed outer rings. Both types can support heavy loads, as well as light unidirectional thrust loads. The thrust load is transmitted between the diagonally opposed rib faces in a sliding action. When limiting thrust conditions are approached, lubrication can become critical. Your Timken representative should be consulted for assistance in such applications. When thrust loads are very light, these bearings may be used in an opposed mounting to locate the shaft. In such cases, shaft endplay should be adjusted at time of assembly.

Types RT and RIT have double ribbed outer and single ribbed inner ring with a loose rib that allow the bearing to provide axial location in both directions. Types RP and RIP have a double-ribbed inner ring and a single-ribbed outer ring with a loose rib.

Types RT and RP (as well as RIT and RIP) can carry heavy radial loads and light thrust loads in both directions. Factors governing the thrust capacity are the same as for types RF and RJ bearings.

A type RT or RP bearing may be used in conjunction with type RN or RU bearings for applications where axial shaft expansion is anticipated. In such cases, the fixed bearing is usually placed nearest the drive end of the shaft to minimize alignment variations in the drive. Shaft endplay (or float) is determined by the axial clearance in the bearing.

The type NU, N, NJ, NF, NUP and NP are similar in construction to their 'R' counterparts, however, they conform to ISO and DIN standards for loose rib rings (thrust collars) and typical industry diameters over or under roller.
A-52xx-WS	A-52xx-WM	52xx-WS	A-52XX

5200 Metric Series

This series features enhanced radial load rating due to its internal design proportions. In this series, the outer ring is double-ribbed and the inner ring is full-width with a cylindrical O.D. The bearing also can be furnished without an inner ring for applications where radial space is limited. When so used, the shaft journal must be hardened to HRC 58 minimum, and the surface finished to 15 RMS maximum.

The bearing is usually furnished with a rugged stamped steel cage ("S" designation) and is land-riding on the outer ring ribs. The cage features depressed bars, which not only space rollers evenly, but retain them as a complete assembly with the outer ring. Cages of machined brass ("M" designation) are available for applications where reversing loads or high speeds might indicate their need. Outer rings are made from bearing quality alloy steel. The inner rings are deep-case hardened to accommodate the hoop stresses resulting from heavy press fits.

The standard bearing is furnished with radial internal clearances designated as R6, tabulated in Radial Cylindrical Roller Section. Other internal clearances can be supplied upon request. Proper roller guidance is assured by integral ribs and roller end clearance control.

BEARING TYPES AND CAGES – *continued*

TAPERED ROLLER BEARINGS

SINGLE-ROW BEARINGS

TS - Single-Row

This is the basic and the most widely used type of tapered roller bearing. It consists of the cone assembly and the cup. It is usually fitted as one of an opposing pair (see choice of mounting configuration). During equipment assembly, single-row bearings can be "set" to the required clearance (endplay) or preload condition to optimize performance.

TS

TSF - Single-row, with flanged cup

Variation on the basic single-row bearing-type TSF has a flanged cup to facilitate axial location and accurately aligned seats in a through-bored housing.

TSF

TWO-ROW BEARINGS

TDO - Double cup

This has a one-piece (double) cup and two single cones. It is usually supplied complete with a cone spacer as a pre-set assembly. This configuration gives a wide effective bearing spread and is frequently chosen for applications where overturning moments are a significant load component. TDO bearings can be used in fixed (locating) positions or allowed to float in the housing bore, for example to compensate for shaft expansion. TDODC or TDOCD cups also are available in most sizes. These cups have holes in the O.D. that permit the use of pins to prevent cup rotation in the housing.

TDI - Double cone
TDIT - Double cone with tapered bore

Both comprise a one-piece (double) cone and two single cups. They are usually supplied complete with a cup spacer as a pre-set assembly. TDI and TDIT bearings can be used at fixed (locating) positions on rotating shaft applications. For rotating housing applications, the double cone of Type TDI can be used to float on the stationary shaft. Type TDIT has a tapered bore to facilitate removal when an interference fit is essential, yet regular removal is required.

TDI   TDIT

TNA - Non-adjustable
TNASW - Non-adjustable with lubricant slots
TNASWE - Non-adjustable with lubricant slots and extended back face rib

These three bearing types are similar to the TDO – comprised of a one-piece (double) cup and two cones. The cone front faces are extended so they abut, eliminating the need for a separate cone spacer. Supplied with a built-in clearance to give a standard setting range, as listed, these bearings provide a solution for many fixed or floating bearing applications where optimum simplicity of assembly is required.

Types TNASW and TNASWE are variations having chamfers and slots on the front face of the cone to provide lubrication through the shaft. Type TNASWE have extended back face ribs on the cones which are ground on the O.D. to allow for the use of a seal or stamped closure – typically for use on stationary shaft applications.

TNA   TNASW   TNASWE

BEARING TYPES AND CAGES *– continued*

SPACER ASSEMBLIES

Any two single-row bearings (Type-TS) can be supplied as a two-row, pre-set, ready-to-fit assembly by the addition of spacers, machined to pre-determined dimensions and tolerances. This principle is adopted in two standard ranges of spacer assemblies listed in the main sections of this guide: types "SS" and "SR".

However, the concept can be applied to produce custom-made two-row bearings to suit specific applications. In addition to providing a bearing that automatically gives a pre-determined setting at assembly without the need for a manual setting, it is possible to modify the assembly width to suit an application, simply by varying the spacer lengths.

SS

SR

SS - Two single-row assembly

Often referred to as "snap-ring assemblies", Type-SS consist of two basic single-row bearings (Type-TS). They are supplied complete with cone and cup spacers to give a pre-determined bearing setting when assembled. Type-SS have a specified setting range to suit the duty of the application. They have a cone spacer and a snap-ring, which also serves as the cup spacer, to give axial location in a through-bored housing.

SR - Set-Right™ assembly

Type-SR are made to a standard setting range, based on Timken's Set-Right™ automated setting technique suitable for most industrial applications. They have two spacers and an optional snap-ring that may be used for axial location. Because both types are made up of popular sizes of single-row bearings, they provide a low cost option for many applications.

THERE ARE THREE BASIC TYPES OF SPACER ASSEMBLIES

TYPE 2TS-IM (INDIRECT MOUNTING)

These consist of two single-row bearings with a cone and cup spacer. In some applications the cup spacer is replaced by a shoulder in the bearing housing.

TYPE 2TS-DM (DIRECT MOUNTING)

These consist of two single-row bearings, with cones abutting and a cup spacer. They are generally used at fixed (locating) positions on rotating shaft applications.

TYPE 2TS-TM (TANDEM MOUNTING)

Where combined radial and thrust load capacity is required, but the thrust component is beyond the capacity of a single bearing (within a given maximum O.D.), two single-row bearings can be mounted in tandem. Appropriate cone and cup spacers are supplied. Consult your Timken representative for the most effective and economical solution.

2TS-IM

2TS-DM

2TS-TM

BEARING TYPES AND CAGES – *continued*

PACKAGED BEARINGS
PINION PAC™   UNIPAC™   UNIPAC–PLUS™   AP™   SP™

Pinion Pac™

The Pinion Pac™ bearing is a ready to install, pre-set and sealed package consisting of two rows of tapered roller bearings mounted in a carrier. It is custom designed for the final drive pinions of heavy commercial vehicles. The package gives the differential pinion builder considerable improvements in reliability, ease of assembly and supply logistics.

UNIPAC™

The UNIPAC™ bearing is a two-row tapered roller bearing, supplied as a maintenance free, pre-set, pre-lubricated and sealed package. Originally designed for the high-volume needs of passenger car wheels, the UNIPAC bearing now has wider application in wheel hubs of heavy vehicles as well as in industrial equipment.

The UNIPAC bearing provides improvements in reliability, ease of assembly and supply logistics.

UNIPAC-PLUS™

The UNIPAC-PLUS™ bearing is a ready-to-install, pre-set, sealed and lubricated-for-life two-row assembly with a flanged outer ring. It is a maintenance-free, heavy vehicle wheel package. The package enables a reduction in the wheel weight by eliminating the traditional wheel hub and has the advantage of improving reliability, assembly and supply logistics. An added advantage for disc-brake equipped axles is ease of mounting.

AP™ Bearing

The AP™ bearing is a self-contained assembly, made in a wide range of sizes. It consists of two single cones, a counterbored double cup, a backing ring, two radial seals, an end cap and cap screws. The AP bearing is supplied as a pre-set, pre-lubricated and sealed package.

SP™ Bearing

Similar in concept to AP bearings, the SP™ bearing is designed specifically for journal bearings on high-speed rail applications. The SP bearing type differs from the AP bearing in that SP bearings have labyrinth seals, are more compact in size, and are manufactured to metric boundary dimensions.

SEALED BEARINGS

TSL

The TSL incorporates a DUO-FACE® PLUS seal, making it an economical choice for grease lubricated applications at moderate speeds.

TSL

A

BEARING TYPES AND CAGES – *continued*

PRECISION BEARINGS

TS and TSF single-row bearings

These bearings are similar in design to the types described on page A11. They are only produced in high-precision quality, to be used in machine tool spindles, printing press cylinders and other applications where accuracy of rotation is required.

TSHR - Hydra-Rib™ bearing with preload adjustment device

For many applications, notably in the machine tool industry, bearings are required to run at high speeds with a controlled preload setting. The Hydra-Rib™ bearing has a "floating" cup rib controlled by hydraulic or pneumatic pressure, which ensures that the required bearing preload is maintained irrespective of the differential expansions or changes in loading taking place within the system.

TSHR

• •

HIGH SPEED BEARINGS

TSMA - Single-row, with axial oil provision

Some applications require extreme high-speed capability, where special lubrication methods must be provided.

The TSMA is a single-row bearing with a special provision for lubrication of the critical roller-rib contact area to ensure adequate lubrication at high speeds. The concept works by capturing oil in a manifold (attached to the cone), which is then directed to the rib-roller contact area through holes drilled axially through the large cone rib. Consult your Timken representative for other high-speed bearing designs with specialized lubrication methods.

TSMA

TXR - Crossed roller bearing

A crossed roller bearing is two sets of bearing races and rollers brought together at right angles – with alternate rollers facing opposite directions – within a section height not much greater than that of a TS bearing. The steep angle, tapered geometry of the bearing causes the load-carrying center of each of the races to be projected along the axis, resulting in a total effective bearing spread many times greater than the width of the bearing itself. This type of bearing offers a high resistance to overturning moments.

The normal design of the bearing is type TXRDO, which has a double cup and two cones, with rollers spaced by polymer separators. Crossed roller bearings are manufactured in precision classes.

TXR

OTHER TWO-ROW BEARINGS

Type TDIE - Extended double cone
Type TDIA

These two-row bearings are designed for applications where it is required to lock the loose-fitted cone to a shaft, with provision also for effective closure or sealing – (typically on pillow blocks, disc-harrow and similar agricultural machinery shafts and line shafts).

Type TDIE is available in two forms: cylindrical bore with the cone extended at both ends and provisions for setscrews and locking collars at each end, or with an inherently self-locking square bore – ideal for farm machinery applications.

Type TDIA is similar to type TDIE with a cylindrical bore. There is a provision for a locking collar at one end only. The compact configuration is suited to pillow blocks and similar applications.

On all types, the hardened and ground O.D. of the cone extension provides an excellent surface for effective closure or sealing.
TDIE
TDIE (Square Bore)

TDIA
Type TNASWH - Non adjustable, heavy-duty, double cup
Type TNASWHF - Non adjustable, heavy-duty, with flanged double cup

These are two-row bearing assemblies with two cones and a one-piece cup, similar to type TNASWE listed in this guide.

The cups have a heavy wall section, allowing the bearings to be used directly as steady rest rollers, in sheet and strip levellers or, with a flange (Type-TNASWHF), as a complete wheel assembly for use on rails.

The cup is extended at both ends and counterbored to accept stamped closures. The bearings can be supplied with these ready-fitted as a unit assembly (but not pre-lubricated).

Rubbing seals are available for certain sizes.

TNASWHF

TNASWH

BEARING TYPES AND CAGES – *continued*

FOUR-ROW BEARING ASSEMBLIES

Four-row bearings combine the inherent high-load, radial/thrust capacity and direct/indirect mounting variations of tapered roller bearings into assemblies of maximum load rating in a minimum space. Their main application is on the roll necks of rolling mill equipment.

All four-row bearings are supplied as pre-set matched assemblies, with all components numbered to ensure correct installation sequence.

Type-TQO
Type-TQOW

These pairs of directly mounted bearings consist of two double cones, two single and one double cup, with a cone spacer and two cup spacers. These types are used on roll necks of low- and medium-speed rolling mills, applied to the necks with a loose fit. When the fillet and/or filler rings do not have lubrication slots, they are provided in the faces of the bearing cones (Type-TQOW). Slots in the cone spacer permit lubricant to flow from the bearing chamber to the roll neck. The cone spacers also are hardened to minimize face wear.
Type-TQITS
Type-TQITSE

The main feature of these bearings is a tapered bore – the taper being matched and continuous through the cones. This permits an interference fit on the backup rolls of high-speed mills, where a loose cone fit of a straight bore type TQO bearing could result in excessive neck wear.

These four-row bearings consist of two pairs of indirectly mounted bearings: two single and one double cone, four single cups and three cup spacers. The relevant faces of the cones are extended so that they abut, eliminating the need for cone spacers. The indirect mounting of the bearing pairs increase the overall effective spread of the bearing, to give optimum stability and roll rigidity.

Type TQITSE is the same as TQITS, but has an extension to the large bore cone adjacent to the roll body. This not only provides a hardened, concentric and smooth surface for radial lip seals, but also improves roll neck rigidity by eliminating a fillet ring. This allows the centerline of the bearing to move closer to the roll body. It also permits shorter and less costly rolls.

TQO

TQOW

TQITS

TQITSE

Sealed roll neck

The sealed roll neck bearing is similar to the TQO. A specially designed sealing arrangement is incorporated in the bearing to endure highly contaminated environments. The special seal design is built into the bearing to eliminate contamination from outside the bearing envelope and extend the useful life.

Sealed Roll Neck Bearing

THRUST BEARINGS

Standard types of thrust bearings manufactured by Timken are included in this section. Each type is designed to take thrust loads, but four types (TVL, DTVL, TTHD and TSR) accommodate radial loads as well. All types reflect advanced design concepts, with large rolling elements for maximum capacity. In roller thrust bearings, controlled contour rollers are used to insure uniform, full-length contact between rollers and raceways with resultant high capacity. Thrust bearings should operate under continuous load for satisfactory performance.

Type TVB – Grooved race thrust ball bearing
Type TVL – Angular contact thrust ball bearing
Type DTVL – Two direction angular contact thrust ball bearing
Type TP – Thrust cylindrical roller bearing
Type TPS – Self-aligning thrust cylindrical roller bearing
Type TTHD – Thrust tapered roller bearing
Type TSR – Thrust spherical roller bearing
Type TTVF – V-Flat thrust tapered roller bearing
Type TTVS – Self-aligning V-Flat thrust tapered roller bearing
Type TTSP – Steering pivot thrust cylindrical roller bearing

A

BEARING TYPES AND CAGES – *continued*

Thrust Ball Bearings

Thrust ball bearings are used for lighter loads and higher speeds than thrust roller bearings.

Type TVB ball thrust bearing is separable and consists of two hardened and ground steel washers with grooved raceways, and a cage that separates and retains precision-ground and lapped balls. The standard cage material is brass, but this may be varied according to the requirements of the application. Timken Standard Tolerances for Type TVB bearings are equivalent to ABEC 1 where applicable, but higher grades of precision are available.

Type TVB bearing provides axial rigidity in one direction and its use to support radial loads is not suggested. Usually the rotating washer is shaft-mounted. The stationary washer should be housed with sufficient O.D. clearance to allow the bearing to assume its proper operating position. In most sizes both washers have the same bore and O.D. The housing must be designed to clear the O.D. of the rotating washer, and it is necessary to step the shaft to clear the bore of the stationary washer.

Type TVL is a separable angular contact ball bearing primarily designed for unidirectional thrust loads. The angular contact design, however, will accommodate combined radial and thrust loads since the loads are transmitted angularly through the balls.

The bearing has two hardened and ground steel rings with ball grooves and a one-piece brass cage that spaces the ball complement. Although not strictly an angular ball bearing, the larger ring is still called the outer ring, and the smaller the inner ring. Timken Standard Tolerances for type TVL bearings are equivalent to ABEC 1 where applicable, but higher grades of precision are available.

Usually the inner ring is the rotating member and is shaft-mounted. The outer ring is normally stationary and should be mounted with O.D. clearance to allow the bearing to assume its proper operating position. If combined loads exist, the outer ring must be radially located in the housing.

Type TVL bearings should always be operated under thrust load. Normally, this presents no problem as the bearing is usually applied on vertical shafts in oil field rotary tables and machine tool indexing tables. If constant thrust load is not present, it should be imposed by springs or other built-in devices.

Low friction, cool running and quiet operation are advantages of this type of TVL bearing, which may be operated at relatively high speeds. The bearing also is less sensitive to misalignment than other types of rigid thrust bearings.

DTVL is similar in design to TVL except the DTVL has an additional washer and ball complement permitting it to carry moderate thrust in one direction and light thrust in the other direction.

Thrust Cylindrical Roller Bearings

Thrust cylindrical roller bearings withstand heavy loads at relatively moderate speeds. Standard bearings can be operated at bearing O.D. peripheral speeds of 3000 fpm (15 m/s). Special design features can be incorporated into the bearing and mounting to attain higher operating speeds.

Because loads are usually high, extreme pressure (EP) lubricants should be used with roller thrust bearings. Preferably, the lubricant should be introduced at the bearing bore and distributed by centrifugal force.

All types of thrust roller bearings are made to Timken Standard Tolerances. Higher precision may be obtained when required.

Type TP thrust cylindrical roller bearing has two hardened and ground steel washers, with a cage retaining one or more controlled contour rollers in each pocket. When two or more rollers are used in a pocket, they are of different lengths and are placed in staggered position in adjacent cage pockets to create overlapping roller paths. This prevents wearing grooves in the raceways and prolongs bearing life.

Because of the simplicity of their design, Type TP bearings are economical. Since minor radial displacement of the raceways does not affect the operation of the bearing, its application is relatively simple and often results in manufacturing economies for the user. Shaft and housing seats, must be square to the axis of rotation to prevent initial misalignment problems.

TP

TPS
Type TPS bearings are the same as Type TP bearings except one washer is spherically ground to seat against an aligning washer, thus making the bearing adaptable to initial misalignment. Its use is not suggested for operating conditions where alignment is continuously changing (dynamic misalignment).

Thrust Spherical Roller Bearings

Type-TSR

The TSR thrust spherical roller bearing design achieves a high thrust capacity with low friction and continuous roller alignment. The bearings can accommodate pure thrust loads as well as combined radial and thrust loads. Typical applications are air regenerators, centrifugal pumps and deep well pumps. Maximum axial misalignment between inner and outer ring is ±2.5 degrees.

TSR

TVB   TVL   DTVL
BEARING TYPES AND CAGES – *continued*

Thrust Tapered Roller Bearings

Type-TTHD

Type TTHD thrust tapered roller bearing has an identical pair of hardened and ground steel washers with conical raceways, and a complement of controlled contour tapered rollers equally spaced by a cage.

In the design of Type TTHD, the raceways of both washers and the tapered rollers have a common vertex at the bearing center. This assures true rolling motion.

TTHD bearings are well-suited for applications such as crane hooks, where extremely high thrust loads and heavy shock must be resisted and some measure of radial location obtained.

For very low-speed, heavily loaded applications, these bearings are supplied with a full complement of rollers for maximum capacity and are identified in the table of dimensions. For application review of the full complement Type TTHD bearing, consult your Timken representative.
TTHD

Type-TTVF   Type-TTVS
Type-TTHDFL   Type-TTHDSV
Type-TTHDSX

V-Flat Tapered Roller bearings (TTVF and TTVS) combine the best features of thrust tapered and cylindrical roller bearings, offering the highest possible capacity of any thrust bearing of its size. V-Flat design includes one flat washer and the second with a tapered raceway matching the rollers. Design was originally developed for screwdown applications in metal rolling mills where thrust loads exceeding one million pounds are common. These bearings have exceptional dynamic capacity within a given envelope and provide superior static capacity. They have been highly successful in heavily loaded extruders, in cone crushers and other applications where a wide range of operating conditions are found.

Most sizes utilize cages with hardened pins through the center of the rollers, allowing closer spacing of the rollers to maximize capacity. Smaller sizes have cast brass cages, carefully machined to permit full flow of lubricant.

Self-aligning V-Flat bearings (TTVS) employ the same basic roller and raceway design, except the lower washer is in two pieces, with the contacting faces spherically ground permitting self-alignment under conditions of initial misalignment. TTVS bearings should not be used if dynamic misalignment (changing under load) is expected.
TTVF   TTVS

TTHDFL   TTHDSV   TTHDSX

TTC - Cageless   TTSP - Steering pivot

There are two basic types of Timken thrust bearings designed for specific fields of duty where the only load component is thrust, TTC and TTSP. The TTC bearing uses a full complement of rollers without a cage and is used when the speeds are slow. The TTSP bearing uses a cage and was designed for the oscillating motion of steering pivot positions.

TTC   TTSP

A

CAGES

Cages (sometimes referred to as rolling element separators or retainers) perform an important function in the proper operation of rolling bearings. They serve to maintain uniform rolling element spacing in the races of the inner and outer rings of the bearings as the rolling elements pass into and out of the load zones. Cage types in several materials and configurations have been developed by Timken to meet various service requirements. Temperature limitations are described later in this section.

Some of the materials from which cages are made include pressed steel, pressed brass, machined brass, machined steel and compositions of various synthetic materials.

STEEL CAGES FOR RADIAL BALL BEARINGS

Steel cages are generally ball-piloted and are available in the following types:

Pressed Steel Finger Type Cages (SR)
Light in weight and made from strong, cold rolled steel, the pressed steel cage because of its compactness is the optimum design for use in shielded and sealed bearings which must conform to ABEC boundary dimensions. This is a general purpose design and is frequently used for ABEC 1 ball bearing sizes.

Pressed Steel Welded Cages (WR)
The welded steel cage provides greater strength, increased rigidity, and better pocket alignment than the finger type. The projection welding of the cage halves eliminates weakening notches or holes and fingers or rivets. It assures better mating of cage halves circumferentially and radially.

This construction also provides more uniformity of ball to pocket clearance. Improved pocket geometry permits higher speeds, reduces cage wear, provides cooler operation, and improves and extends lubricant life. This cage is standard in most radial non-filling slot bearings of the open, shielded, and sealed types.

MOLDED CAGES FOR RADIAL BALL BEARINGS

Molded cages are either ball piloted or land piloted and are available in the following types:

Nylon (PRB)
One-piece molded snap-in 6/6 nylon cages are specially processed to provide:
- Toughness at moderately high and low temperatures
- Resistance to abrasion
- Resistance to organic solvents, oils and grease
- Natural lubricity
- Long term service at temperatures up to +120° C (+250° F)
- Dimensional stability

These cages offer superior performance in applications involving misalignment due to their greater flexibility.

PRB molded nylon cages provide uniformity of ball pocket clearances for consistent operation. They are suitable for temperatures up to +120° C (+250° F) continuous operation and can tolerate +150° C (+300° F) for short periods.

These cages are available in conrad (K) bearings and are standard for the more popular wide inner ring bearing series.

BEARING TYPES AND CAGES – *continued*

Reinforced Nylon (PRC)

Molded 6/6 nylon reinforced with 30 percent (by weight) glass fibers. This material is used primarily for one-piece ring piloted cages used in precision grades of angular contact bearings.

PRC cages offer outstanding strength and long term temperature resistance. Molded to very close tolerances and uniformity, combined with light weight design, they permit higher speeds and reduced noise. They are suitable for temperatures up to +150˚ C (+300° F).

PRC cages are usually the one piece outer piloted "L" type design, but are also available in one piece ball controlled designs.

Brass and Steel Cages

Brass cages are generally installed in bearings which are designed for use on heavily loaded applications, such as, deep well pumps, woodworking machinery, and heavy construction machinery. The following types of Timken brass cages are available:

Iron Silicon Brass Cage (SMBR) and Machined Steel Cage (MSR)

The SMBR and MSR cages are ring piloted. The advantages of these cages are high strength even at elevated temperatures (see chart on page A167) as well as high-speed capability due to the ring piloted construction. In many cases these cages are silver plated for use in applications requiring high reliability.

They are available in both ball and roller bearings.

Cast Brass Cage (BR)

This cage, a ball piloted brass retainer designated by the letters BR, utilizes two identical halves which are riveted together.

Composition Cages (CR)

Composition cages combine light weight, precision and oil-absorbing features which are particularly desirable for use on high speed applications. This (CR) cage, is a ring piloted type and is particularly associated with the outer-ring piloted , extra precision WN series bearings.

Special Cages

For certain very high contact angle, light section aircraft bearings, molded nylon "snake" cages are employed. Cages are also made with high temperature materials (see page A167) in the various configurations described above.

For availability of special cages please contact your Timken representative.

Special Molded Cages

For very high speeds or very high temperature applications special materials can be used. Nylon with a PTFE additive is available for molded cages required for high speed applications. For applications involving high operating temperatures (up to +232° C, +450° F) molded cages made of fiber reinforced polyphenelyene sulfide can be made.

For availability of these special cages please consult your Timken representative.

BR   MBR

Machined Brass Cage (MBR)

These cages are machined all over to provide ring riding surfaces and good static and dynamic balance. They are commonly incorporated as inner ring piloted designs in the 7000 angular contact product family. Because of their superior strength, these cages are generally used on heavily loaded applications such as, deep well pumps, woodworking machinery, and heavy construction machinery.

A

CAGES FOR SPHERICAL ROLLING BEARINGS

Brass Cages

YM Bearing cages are one-piece design centrifugally cast and precision machined. The rugged construction of this cage type provides an advantage in more severe applications. Due to its design this cage permits YM bearings to incorporate greater load carrying capabilities.

The open end design permits lubricant to reach all surfaces easily assuring ample lubrication and a cooler running bearing.

Stamped Steel Cages (CJ)

These cages are used in CJ bearings and are designed to permit extra load carrying capabilities in the bearing. Two independent cages, one for each row of rollers, are assembled in an individual bearing.

Pin Type Cages

Large diameter spherical roller bearings can be supplied with these cages. The design of pin type cages permits an increased roller complement thus giving the bearing enhanced load carrying ability. Consult your Timken representative for suggestions on the application of this cage.

YM Cage   CJ

CAGES FOR RADIAL CYLINDRICAL ROLLER BEARINGS

Brass Cages

These are primarily roller guided cages with cylindrical bored pockets. They are used with the standard style roller bearings.

Stamped Steel Cages

Stamped steel cages of varying designs are available in the standard style cylindrical roller bearings.

The stamped steel cage for the 5200 series is a land riding cage piloted by the outer ring ribs. The cage features depressed bars which not only space rollers evenly but retain them as a complete assembly with the outer ring.

Brass Cage

CAGES FOR TAPERED ROLLER BEARINGS

Stamped Steel Cages

The cages are of compact space savings design and in some cases permit increased load-carrying capabilities to be incorporated into the bearing. They are roller riding with bridges positioned above the pitch line to retain the rollers within the cone.

Machined Cages

These heavy section ruggedly constructed cages are fully machined and are land riding on the thrust and toe flange O.D. of the cone (inner ring). The bridges between the straight through machined roller pockets are staked above the pitch line to retain the rollers with the cone.

Pin Type Cages

This steel cage design features a pin which fits closely with a bored hole in the roller. The rollers can thus be retained with a minimum space between the rollers so that an increased complement of rollers can be incorporated. This results in greater load carrying capabilities in the bearing.

DETERMINATION OF APPLIED LOADS AND BEARING ANALYSIS

SUMMARY OF SYMBOLS USED TO DETERMINE APPLIED LOADS AND BEARING ANALYSIS

Symbol	Description	Units
a_1	Reliability Life Factor	
a_2	Material Life Factor	
a_3	Operating Condition Life Factor	
a_{3d}	Debris Life Factor	
a_{3h}	Hardness Life Factor	
a_{3k}	Load Zone Life Factor	
a_{3l}	Lubrication Life Factor	
a_{3m}	Misalignment Life Factor	
a_{3p}	Low Load Life Factor	
a_e	Effective Bearing Spread	mm, in.
b	Tooth Length	mm, in.
c_1, c_2	Linear Distance (positive or negative)	mm, in.
C	Dynamic Radial Load Rating	N, lbf
C_0	Static Load Rating	N, lbf
C_p	Specific Heat of Lubricant	J/(kg -C°), BTU/(lb x F°)
d	Bearing bore diameter	mm, in.
d_0	Mean inner race diameter	mm, in.
d_c	Distance Between Gear Centers	mm, in.
d_m	Mean Bearing Diameter	mm, in.
d_s	Shaft inside diameter	mm, in.
D	Bearing outside diameter	mm, in.
D_0	Mean outer race diameter	mm, in.
D_H	Housing outside diameter	mm, in.
D_m	Mean Diameter or Effective Working Diameter of a Sprocket, Pulley, Wheel or Tire Also, Tapered Roller Mean Large Rib Diameter	mm, in.
D_{mG}	Mean or Effective Working Diameter of the Gear	mm, in.
D_{mP}	Effective Working Diameter of the Pinion	mm, in.
D_{mW}	Effective Working Diameter of the Worm	mm, in.
D_{pG}	Pitch Diameter of the Gear	mm, in.
D_{pP}	Pitch Diameter of the Pinion	mm, in.
D_{pW}	Pitch Diameter of the Worm	mm, in.
e	Life Exponent	
f	Lubricant Flow Rate	L/min, U.S. pt/min
f_0	Viscous Dependent Torque Coefficient	
f_1	Load Dependent Torque Coefficient	
f_B	Belt or Chain Pull Factor	
F	General Term for Force	N, lbf
F_a	Applied Thrust (Axial) Load	N, lbf
F_{ai}	Induced Thrust (Axial) Load due to Radial Loading	N, lbf
F_{ac}	Induced Thrust (Axial) Load due to Centrifugal Loading	N, lbf
F_{aG}	Thrust Force on Gear	N, lbf
F_{aP}	Thrust Force on Pinion	N, lbf
F_{aW}	Thrust Force on Worm	N, lbf
f_B	Belt or Chain Pull	N, lbf
F_c	Centrifugal Force	N, lbf
F_r	Applied Radial Load	N, lbf
F_{sG}	Separating Force on Gear	N, lbf
F_{sP}	Separating Force on Pinion	N, lbf
F_{sW}	Separating Force on Worm	N, lbf
F_{te}	Tractive Effort on Vehicle Wheels	N, lbf
F_{tG}	Tangential Force on Gear	N, lbf
F_{tP}	Tangential Force on Pinion	N, lbf
F_{tW}	Tangential Force on Worm	N, lbf
F_W	Force of Unbalance	N, lbf
h	Horizontal (used as subscript)	
H	Power (kW or HP)	kW, HP
HF_s	Static Load Rating Adjustment Factor for Raceway Hardness	

Symbol	Description	Units
k	Centrifugal Force Constant	lbf/RPM^2
k_1	Bearing Torque Constant	
k_4, k_5, k_6	Dimensional Factor to calculate heat generation	
K	Tapered Roller Bearing Radial-to-Axial Dynamic Load Rating Factor	
l	Thrust Needle Roller Length	mm, in.
L	Lead. Axial Advance of a Helix for One Complete Revolution	mm, in.
L	Distance between bearing geometric center lines	mm, in.
m	Gearing Ratio	
M	Bearing Operating Torque or Moment	N-m, N-mm, lb-in.
n	Bearing Operating Speed or General Term for Speed	rot/min, RPM
n_G	Gear Operating Speed (RPM)	rot/min, RPM
n_P	Pinion Operating Speed (RPM)	rot/min, RPM
n_W	Worm Operating Speed (RPM)	rot/min, RPM
N_G	Number of Teeth in the Gear	
N_P	Number of Teeth in the Pinion	
N_S	Number of Teeth in the Sprocket

DETERMINATION OF APPLIED LOADS AND BEARING ANALYSIS - *continued*

DETERMINATION OF APPLIED LOADS

The following equations are used to determine the forces developed by machine elements commonly encountered in bearing applications.

GEARING

Spur gearing (Fig. A-1)
Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H}{D_{pG} n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{pG} n_G} \quad \text{(lbf-in.)}$$

Separating force

$$F_{sG} = F_{tG} \tan \phi_G$$

Fig. A-1
Spur gearing.
Single helical gearing (Fig. A-2)
Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H}{D_{pG} n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{pG} n_G} \quad \text{(lbf-in.)}$$

Separating force

$$F_{sG} = \frac{F_{tG} \tan \phi_G}{\cos \psi_G}$$

Thrust force

$$F_{aG} = F_{tG} \tan \psi_G$$

Fig. A-2
Helical gearing.
Straight bevel and zerol gearing with zero degrees spiral (Fig. A-3)

In straight bevel and zerol gearing, the gear forces tend to push the pinion and gear out of mesh, such that the direction of the thrust and separating forces are always the same regardless of direction of rotation. (Fig. A-3) In calculating the tangential force, (F_{tP} or F_{tG}), for bevel gearing, the pinion or gear mean diameter, (D_{mP} or D_{mG}), is used instead of the pitch diameter, (D_{pP} or D_{pG}). The mean diameter is calculated as follows:

$$D_{mG} = D_{pG} - b \sin \gamma_G \qquad \text{or} \qquad D_{mP} = D_{pP} - b \sin \gamma_P$$

In straight bevel and zerol gearing

$$F_{tP} = F_{tG}$$

Fig. A-3
Straight bevel and zerol gears – thrust and separating forces are always in same direction regardless of direction of rotation.
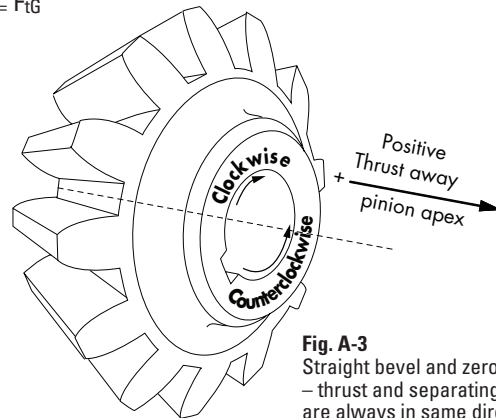

Pinion
Tangential force

$$F_{tP} = \frac{(1.91 \times 10^7)\, H}{D_{mP}\, n_P} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{mP}\, n_P} \quad \text{(lbf-in.)}$$

Thrust force

$$F_{\phi P} = F_{tP} \tan \phi_P \sin \gamma_P$$

Separating force

$$F_{sP} = F_{tP} \tan \phi_P \cos \gamma_P$$

Straight bevel gear (Fig. A-4)

Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H}{D_{mG}\, n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{mG}\, n_G} \quad \text{(lbf-in.)}$$

Fig. A-4
Straight bevel gearing.

Thrust force

$$F_{aG} = F_{tG} \tan \phi_G \sin \gamma_G$$

Separating force

$$F_{sG} = F_{tG} \tan \phi_G \cos \gamma_G$$

Spiral bevel and hypoid gearing (Fig. A-5)

In spiral bevel and hypoid gearing, the direction of the thrust and separating forces depends upon spiral angle, hand of spiral, direction of rotation, and whether the gear is driving or driven (see Table 1). The hand of the spiral is determined by noting whether the tooth curvature on the near face of the gear (Fig. A-5) inclines to the left or right from the shaft axis. Direction of rotation is determined by viewing toward the gear or pinion apex.

In spiral bevel gearing

$$F_{tP} = F_{tG}$$

In hypoid gearing

$$F_{tP} = \frac{F_{tG} \cos \psi_P}{\cos \psi_G}$$

Hypoid pinion effective working diameter

$$D_{mP} = D_{mG} \left(\frac{N_p}{N_G} \right)\left(\frac{\cos \psi_G}{\cos \psi_P} \right)$$
Fig. A-5
Spiral bevel and hypoid gears – the direction of thrust and separating forces depends upon spiral angle, hand of spiral, direction of rotation, and whether the gear is driving or driven.

Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H}{D_{mG}\, n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{mG}\, n_G} \quad \text{(lbf-in.)}$$

Hypoid gear effective working diameter

$$D_{mG} = D_{pG} - b \sin \gamma_G$$
Fig. A-6
Spiral bevel and hypoid gearing.

TABLE 1

SPIRAL BEVEL AND HYPOID GEARING EQUATIONS

Driving member rotation	Thrust force	Separating force
Right hand spiral clockwise or Left hand spiral counterclockwise	Driving member $F_{aP} = \dfrac{F_{tP}}{\cos \psi_P} \ (\tan \phi_P \sin \gamma_{P} - \sin \psi_P \cos \gamma_{P})$	Driving member $F_{sP} = \dfrac{F_{tP}}{\cos \psi_P} \ (\tan \phi_P \cos \gamma_{P} + \sin \psi_P \sin \gamma_{P})$
	Driven member $F_{aG} = \dfrac{F_{tG}}{\cos \psi_G} \ (\tan \phi_G \sin \gamma_{G} + \sin \psi_G \cos \gamma_{G})$	Driven member $F_{sG} = \dfrac{F_{tG}}{\cos \psi_G} \ (\tan \phi_G \cos \gamma_{G} - \sin \psi_G \sin \gamma_{G})$
Right hand spiral counterclockwise or Left hand spiral clockwise	Driving member $F_{aP} = \dfrac{F_{tP}}{\cos \psi_P} \ (\tan \phi_P \sin \gamma_{P} + \sin \psi_P \cos \gamma_{P})$	Driving member $F_{sP} = \dfrac{F_{tP}}{\cos \psi_P} \ (\tan \phi_P \cos \gamma_{P} - \sin \psi_P \sin \gamma_{P})$
	Driven member $F_{aG} = \dfrac{F_{tG}}{\cos \psi_G} \ (\tan \phi_G \sin \gamma_{G} - \sin \psi_G \cos \gamma_{G})$	Driven member $F_{sG} = \dfrac{F_{tG}}{\cos \psi_G} \ (\tan \phi_G \cos \gamma_{G} + \sin \psi_G \sin \gamma_{G})$

Straight worm gearing (Fig. A-7)

WORM

Tangential force

$$F_{tW} = \frac{(1.91 \times 10^7) \, H}{D_{pW} \, n_W} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5) \, H}{D_{pW} \, n_W} \quad \text{(lbf-in.)}$$

Thrust force

$$F_{aW} = \frac{(1.91 \times 10^7) \, H \, \eta}{D_{pG} \, n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5) \, H \, \eta}{D_{pG} \, n_G} \quad \text{(lbf-in.)}$$

or

$$F_{aW} = \frac{F_{tW} \, \eta}{\tan \lambda}$$

Separating force

$$F_{sW} = \frac{F_{tW} \sin \Phi}{\cos \Phi \, \sin \lambda + \mu \, \cos \lambda}$$
Fig. A-7
Straight worm gearing.

DETERMINATION OF APPLIED LOADS AND BEARING ANALYSIS - *continued*

Worm Gear

Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H\, \eta}{D_{pG}\, n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H\, \eta}{D_{pG}\, n_G} \quad \text{(lbf-in.)}$$

or

$$F_{tG} = \frac{F_{tW}\, \eta}{\tan \lambda}$$

Thrust force

$$F_{aG} = \frac{(1.91 \times 10^7)\, H}{D_{pW}\, n_W} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{pW}\, n_W} \quad \text{(lbf-in.)}$$

Separating force

$$F_{sG} = \frac{F_{tW}\, \sin \Phi}{\cos \Phi\, \sin \lambda + \mu\, \cos \lambda}$$

where:

$$\lambda = \tan^{-1} \left(\frac{D_{pG}}{m\, D_{pW}} \right) = \tan^{-1} \left(\frac{L}{\pi\, D_{pW}} \right)$$

$$\eta = \frac{\cos \Phi - \mu\, \tan \lambda}{\cos \Phi + \mu\, \cot \lambda}$$

Metric system

$$\mu^* = (5.34 \times 10^{-7})\, V_r^3 + \frac{0.146}{V_r^{0.09}} - 0.103$$

$$V_r = \frac{D_{pW}\, n_W}{(1.91 \times 10^4)\, \cos \lambda} \quad \text{(meters per second)}$$

Inch system

$$\mu^* = (7 \times 10^{-14})\, V_r^3 + \frac{0.235}{V_r^{0.09}} - 0.103$$

$$V_r = \frac{D_{pW}\, n_W}{3.82\, \cos \lambda} \quad \text{(feet per minute)}$$

*Approximate coefficient of friction for the 0.015 to 15 m/s (3 to 3000 ft/min) rubbing velocity range.

Double enveloping worm gearing

Worm

Tangential force

$$F_{tW} = \frac{(1.91 \times 10^7)\, H}{D_{mW}\, n_W} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{mW}\, n_W} \quad \text{(lbf-in.)}$$

Thrust force

$$F_{aW} = 0.98\, F_{tG}$$

Use this value for calculating torque in subsequent gears and shafts. For bearing loading calculations, use the equation for F_{aW}.

Separating force

$$F_{sW} = \frac{0.98\, F_{tG}\, \tan \Phi}{\cos \lambda}$$

WORM GEAR

Tangential force

$$F_{tG} = \frac{(1.91 \times 10^7)\, H\, m\, \eta}{D_{pG}\, n_W} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H\, m\, \eta}{D_{pG}\, n_W} \quad \text{(lbf-in.)}$$

Use this value for F_{tG} for bearing loading calculations on worm gear shaft. For torque calculations, use the following F_{tG} equations.

or

$$F_{tG} = \frac{(1.91 \times 10^7)\, H\, \eta}{D_{pG}\, n_G} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H\, \eta}{D_{pG}\, n_G} \quad \text{(lbf-in.)}$$

Thrust force

$$F_{aG} = \frac{(1.91 \times 10^7)\, H}{D_{mW}\, n_W} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H}{D_{mW}\, n_W} \quad \text{(lbf-in.)}$$

Separating force

$$F_{sG} = \frac{0.98\, F_{tG}\, \tan \Phi}{\cos \lambda}$$

where:

η = efficiency (refer to manufacturer's catalog)

$D_{mW} = 2d_c - 0.98\, D_{pG}$

Lead angle at center of worm

$$\lambda = \tan^{-1} \left(\frac{D_{pG}}{m\, D_{pW}} \right) = \tan^{-1} \left(\frac{L}{\pi\, D_{pW}} \right)$$

DETERMINATION OF APPLIED LOADS AND BEARING ANALYSIS - *continued*

Belt and chain drive factors (Fig. A-8)

Due to the variations of belt tightness as set by various operators, an exact equation relating total belt pull to tension F1 on the tight side and tension F2 on the slack side (Fig. A-8) is difficult to establish. The following equation and Table 2 may be used to estimate the total pull from various types of belt and pulley, and chain and sprocket designs:

$$F_b = \frac{(1.91 \times 10^7)\, H\, f_B}{D_m\, n} \quad \text{(newtons)}$$

$$= \frac{(1.26 \times 10^5)\, H\, f_B}{D_m\, n} \quad \text{(lbf-in.)}$$

Standard roller chain sprocket mean diameter

$$D_m = \frac{P}{\sin\left(\dfrac{180}{N_s}\right)}$$
Fig. A-8

CENTRIFUGAL FORCE

Centrifugal force resulting from imbalance in a rotating member:

$$F_c = \frac{F_w\, r\, n^2}{8.94 \times 10^5} \quad \text{(newtons)}$$

$$= \frac{F_w\, r\, n^2}{3.52 \times 10^4} \quad \text{(lbf-in.)}$$

SHOCK LOADS

It is difficult to determine the exact effect that shock loading has on bearing life. The magnitude of the shock load depends on the masses of the colliding bodies, their velocities, and deformations at impact.

The effect on the bearing depends on how much of the shock is absorbed between the point of impact and the bearings, as well as whether the shock load is great enough to cause bearing damage. It also is dependent on frequency and duration of shock loads.

At a minimum, a suddenly applied load is equivalent to twice its static value. It may be considerably more than this, depending on the velocity of impact.

Shock involves a number of variables that generally are not known or easily determined. Therefore, it is good practice to rely on experience. The Timken Company has years of experience with many types of equipment under the most severe loading conditions. Your Timken representative should be consulted on any application involving unusual loading or service requirements.

GENERAL FORMULAS

Tractive effort and wheel speed

The relationships of tractive effort, power, wheel speed and vehicle speed are:

$$H = \frac{F_{te}\, V}{3600} \quad \text{(kW)}$$

$$n = \frac{5300\, V}{D_m} \quad \text{(rev/min)}$$

Inch system

$$H = \frac{F_{te}\, V}{375} \quad \text{(HP)}$$

$$n = \frac{336\, V}{D_m} \quad \text{(rev/min)}$$

Torque to power relationship

Metric system

$$T = \frac{60\,000\, H}{2\pi\, n} \quad \text{(N-m)}$$

$$H = \frac{2\pi\, n\, T}{60\,000} \quad \text{(kW)}$$

Inch system

$$T = \frac{395\,877\, H}{2\pi\, n} \quad \text{(lbf-in.)}$$

$$H = \frac{2\pi\, n\, T}{395\,877} \quad \text{(HP)}$$

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE

BEARING REACTIONS

Equations and procedure for determining bearing reactions follow.

Effective spread

When a load is applied to a tapered roller or angular contact ball bearing, the internal forces at each rolling element to outer raceway contact act normal to the raceway. These forces have radial and axial components. With the exception of the special case of pure thrust loads, the inner ring and the shaft will experience moments imposed by the asymmetrical axial components of the forces on the rollers.

It can be demonstrated mathematically that, if the shaft is modeled as being supported at its effective bearing center rather than at its geometric bearing center, the bearing moment may be ignored when calculating radial loads on the bearing. Only externally applied loads need to be considered, and moments are taken about the effective centers of the bearings to determine bearing loads or reactions. Fig. A-9 shows single-row bearings in a direct and indirect mounting configuration. The choice of whether to use direct or indirect mounting depends upon the application and duty.

INDIRECT MOUNTING – Tapered Roller Bearing
(Back-to-Back – Angular Contact Ball Bearings)

DIRECT MOUNTING – Tapered Roller Bearing
(Face-to-Face – Angular Contact Ball Bearings)
Fig. A-9
Choice of mounting configuration for single-row bearings, showing position of effective load carrying centers.

Shaft on two supports

Simple beam equations are used to translate the externally applied forces on a shaft into bearing reactions acting at the bearing effective centers.

With two-row tapered and angular contact ball bearings, the geometric center of the bearing is considered to be the support point except where the thrust force is large enough to unload one row. Then, the effective center of the loaded row is used as the point from which bearing load reactions are calculated. These approaches approximate the load distribution within a two-row bearing, assuming rigid shaft and housing. These are statically indeterminate problems in which shaft and support rigidity can significantly influence bearing loading and require the use of computer programs to solve.

Shaft on three or more supports

The equations of static equilibrium are insufficient to solve bearing reactions on a shaft having more than two supports. Such cases can be solved using computer programs if adequate information is available.

In such problems, the deflections of the shaft, bearings and housings affect the distribution of loads. Any variance in these parameters can significantly affect bearing reactions.

CALCULATION EQUATIONS

Symbols Used		
a_e	Effective bearing spread	mm, in.
A, B, ...	Bearing position, used as subscripts	
$c_1, c_2, ...$	Linear distance (positive or negative)	mm, in.
D_{pG}	Pitch diameter of the gear	mm, in.
F	Applied force	N, lbf
F_r	Radial bearing load	N, lbf
h	Horizontal (used as subscript)	
M	Moment	N-mm, lbf-in.
v	Vertical (used as subscript)	
θ_1	Gear mesh angle relative to plane of reference defined in Figure A-10	degree
θ_2	Angle of applied force relative to plane of reference defined in Figure A-10	degree
θ_3	Angle of applied moment relative to plane of reference defined in Figure A-10	degree
Fig. A-10
Bearing radial reactions.

Bearing radial loads are determined by:
1. Resolving forces applied to the shaft into horizontal and vertical components, relative to a convenient reference plane.
2. Taking moments about the opposite support.
3. Combining the horizontal and vertical reactions at each support into one resultant load.

Shown are equations for the case of a shaft on two supports with gear forces F_t (tangential), F_s (separating), and F_a (thrust), an external radial load F, and an external moment M. The loads are applied at arbitrary angles (θ_1, θ_2, and θ_3) relative to the reference plane indicated in Fig. A-10. Using the principle of superposition, the equations for vertical and horizontal reactions (F_{rv} and F_{rh}) can be expanded to include any number of gears, external forces or moments. Use signs as determined from gear force equation.

Care should be used when doing this to ensure proper supporting degrees of freedom are used. That is, tapered roller bearings and ball bearings support radial loads, moment loads and thrust loads in both directions. Spherical roller bearings will not support a moment load, but will support radial and thrust loads in both directions. Cylindrical roller bearings support radial and moment loading, but can only support slight thrust loads depending upon thrust flange configuration. Finally, needle roller bearings only support radial and moment loading.

Vertical reaction component at bearing position B

$$F_{rBv} = \frac{1}{a_e}\left[c_1 (F_{sG} \cos \theta_1 + F_{tG} \sin \theta_1) + \frac{1}{2}(D_{pG} - b \sin \gamma_G) F_{aG} \cos \theta_1 + c_2 F \cos \theta_2 + M \cos \theta_3\right]$$

Horizontal reaction component at bearing position B

$$F_{rBh} = \frac{1}{a_e}\left[c_1 (F_{sG} \sin \theta_1 - F_{tG} \cos \theta_1) + \frac{1}{2}(D_{pG} - b \sin \gamma_G) F_{aG} \sin \theta_1 + c_2 F \sin \theta_2 + M \sin \theta_3\right]$$

Vertical reaction component at bearing position A

$$F_{rAv} = F_{sG} \cos \theta_1 + F_{tG} \sin \theta_1 + F \cos \theta_2 - F_{rBv}$$

Horizontal reaction component at bearing position A

$$F_{rAh} = F_{sG} \sin \theta_1 - F_{tG} \cos \theta_1 + F \sin \theta_2 - F_{rBh}$$

Resultant radial reaction

$$F_{rA} = (F_{rAv}^2 + F_{rAh}^2)^{1/2}$$

$$F_{rB} = (F_{rBv}^2 + F_{rBh}^2)^{1/2}$$

A

Equivalent dynamic radial bearing loads (P_r)

To calculate the L_{10} life, it is necessary to calculate a dynamic equivalent radial load, designated by P_r. The dynamic equivalent radial load is defined as a single radial load that, if applied to the bearing, will result in the same life as the combined loading under which the bearing operates.

$$P_r = XF_r + Y_1F_a$$

Where,

P_r = Dynamic Equivalent Radial Load
F_r = Applied Radial Load
F_a = Applied Axial Load
X = Radial Load Factor
Y = Axial Load Factor

For spherical roller bearings, the values for X and Y can be determined using the equations below. Calculate the ratio of the axial load to the radial load. Compare this ratio to the e value for the bearing.

In equation form,

$$P_r = F_r + Y_2 F_a \qquad \text{for } F_a/F_r \leq e, \text{ and}$$

$$P_r = 0.67F_r + Y_2 F_a \quad \text{for } F_a/F_r > e.$$

Note that values for e, Y_1 and Y_2 are available in the bearing tables.

Needle roller bearings are designed to carry radial load with zero thrust load under normal conditions. With the thrust load equal to zero equivalent radial load (Pr) is equal to the design radial load (Fr). Your Timken representative should be consulted on any applications where thrust load is involved, as the resulting increase in internal friction may require cooling to prevent increased operating temperatures.

For cylindrical roller bearings with purely radial applied load:

$$P = F_r \text{ (kN)}$$

Note: The maximum dynamic radial load that may be
applied to a cylindrical roller bearing should be $\leq C/3$.

If, in addition to the radial load, an axial load F_a acts on the bearing, this axial load is taken into consideration when calculating the life of a bearing (with $F_a \leq F_{az}$; F_{az} is the allowable axial load).

Dimension Series	Load ratio	Equivalent Dynamic Load
10.. 2..E, 3..E	$F_a/F_r \leq 0.11$	$P = F_r$
	$F_a/F_r > 0.11$	$P = 0.93 \cdot F_r + 0.69 \cdot F_a$
22..E, 23..E	$F_a/F_r \leq 0.17$	$P = F_r$
	$F_a/F_r > 0.17$	$P = 0.93 \cdot F_r + 0.45 \cdot F_a$

Tapered roller bearings use the equations based on the number of rows and type of mounting utilized. For single-row bearings in direct or indirect mounting, the table on page A31 can be used based on the direction of the externally applied thrust load. Once the appropriate design is chosen, review the table and check the thrust condition to determine which thrust load and dynamic equivalent radial load calculations apply.

A

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

For ball bearings, the dynamic equivalent radial load can be found in Table 3. The required Y factors are found in the Table 4.

Equivalent Dynamic Thrust Bearing Loads (P_a)

For thrust ball, cylindrical and tapered roller bearings, the existence of radial loads introduces complex load calculations that must be carefully considered. If radial load is zero, the equivalent dynamic thrust load (P_a) will be equal to the applied thrust load (F_a). If any radial load is expected in the application, consult your Timken representative for advice on bearing selection.

For thrust angular contact ball bearings, the equivalent dynamic thrust load is determined by:

$$P_a = X_r F + YF_a$$

The minimum permissible thrust load to radial load ratios (F_a/F_r) and X and Y factors are listed in the bearing dimension tables in the thrust bearing section.

Thrust spherical roller bearing dynamic thrust loads are determined by:

$$P_a = 1.2F_r + F_a$$

Radial load (F_r) of a thrust spherical roller bearing is proportional to the applied axial load (F_a) with $F_r \leq 0.55\, F_a$. Because of the steep roller angle and the fact that the bearing is separable, a radial load will induce a thrust component ($F_{ai} = 1.2\, F_r$), that must be resisted by another thrust bearing on the shaft or by an axial load greater than F_{ai}.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

BEARING EQUIVALENT LOADS AND REQUIRED RATINGS FOR TAPERED ROLLER BEARINGS

Tapered roller bearings are ideally suited to carry all types of loadings - radial, thrust, and any combination of both. Due to the tapered design of the bearing, a radial load will induce a thrust reaction within the bearing which must be opposed by an equal or greater thrust load in order to keep the bearing cone and cup from separating. The ratio of the radial to the thrust load and the bearing included cup angle determine the load zone in a given bearing. The number of rollers in contact as a result of this ratio determines the load zone in the bearing. If all the rollers are in contact, the load zone is referred to as being 360 degrees.

When only radial load is applied to a tapered roller bearing, for convenience it is assumed in using the traditional calculation method that half the rollers support the load – the load zone is 180 degrees. In this case, induced bearing thrust is:

$$F_{a(180)} = \frac{0.47 \, F_r}{K}$$

The equations for determining bearing thrust reactions and equivalent radial loads in a system of two single-row bearings are based on the assumption of a 180-degree load zone in one of the bearings and 180 degrees or more in the opposite bearing.

Dynamic Equivalent Radial Load

The basic dynamic radial load rating, C_{90}, is assumed to be the radial load carrying capacity with a 180-degree load zone in the bearing. When the thrust load on a bearing exceeds the induced thrust, $F_{a(180)}$, a dynamic equivalent radial load must be used to calculate bearing life.

The dynamic equivalent radial load is that radial load which, if applied to a bearing, will give the same life as the bearing will attain under the actual loading.

The equations presented give close approximations of the dynamic equivalent radial load assuming a 180-degree load zone in one bearing and 180 degrees or more in the opposite bearing.

Tapered roller bearings use the equations based on the number of rows and type of mounting utilized. For single-row bearings in direct or indirect mounting, the following table can be used based on the direction of the externally applied thrust load. Once the appropriate design is chosen, review the table and check the thrust condition to determine which thrust load and dynamic equivalent radial load calculations apply.

SINGLE-ROW MOUNTING

To use this table for a single-row mounting, determine if bearings are direct or indirect mounted and to which bearing, A or B, thrust F_{ae} is applied. Once the appropriate design is established, follow across the page opposite that design, and check to determine which thrust load and dynamic equivalent radial load equations apply.

Design	Thrust Condition	Thrust Load	Dynamic Equivalent Radial Load
	$\dfrac{0.47 \, F_{rA}}{K_A} \leq \left(\dfrac{0.47 \, F_{rB}}{K_B} + F_{ae} \right)$	$F_{aA} = \dfrac{0.47 \, F_{rB}}{K_B} + F_{ae}$ $F_{aB} = \dfrac{0.47 \, F_{rB}}{K_B}$	$*P_A = 0.4 \, F_{rA} + K_A \, F_{aA}$ $P_B = F_{rB}$
	$\dfrac{0.47 \, F_{rA}}{K_A} > \left(\dfrac{0.47 \, F_{rB}}{K_B} + F_{ae} \right)$	$F_{aA} = \dfrac{0.47 \, F_{rA}}{K_A}$ $F_{aB} = \dfrac{0.47 \, F_{rA}}{K_A} - F_{ae}$	$P_A = F_{rA}$ $*P_B = 0.4 \, F_{rB} + K_B \, F_{aB}$
	$\dfrac{0.47}{K_B} \leq \left(\dfrac{0.47 \, F_{rA}}{K_A} + F_{ae} \right)$	$F_{aA} = \dfrac{0.47 \, F_{rA}}{K_A}$ $F_{aB} = \dfrac{0.47 \, F_{rA}}{K_A} + F_{ae}$	$P_A = F_{rA}$ $*P_B = 0.4 \, F_{rB} + K_B \, F_{aB}$
	$\dfrac{0.47 \, F_{rB}}{K_B} > \left(\dfrac{0.47 \, F_{rA}}{K_A} + F_{ae} \right)$	$F_{aA} = \dfrac{0.47 \, F_{rB}}{K_B} - F_{ae}$ $F_{aB} = \dfrac{0.47 \, F_{rB}}{K_B}$	$*P_A = 0.4 \, F_{rA} + K_A \, F_{aA}$ $P_B = F_{rB}$
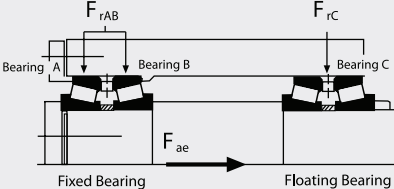

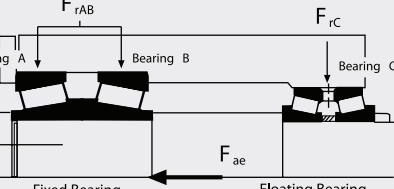

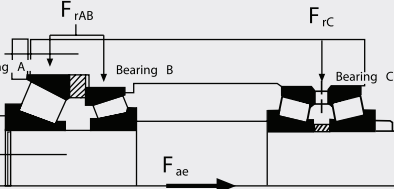

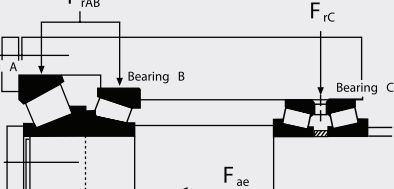

* If $P_A < F_{rA}$, use $P_A = F_{rA}$ and if $P_B < F_{rB}$, use $P_B = F_{rB}$.

A

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

TWO-ROW MOUNTING, FIXED OR FLOATING (WITH NO EXTERNAL THRUST, $F_{AE} = 0$) SIMILAR BEARING SERIES

For double-row tapered roller bearings, the following table can be used. In this table, only bearing A has an applied thrust load. If bearing B has the applied thrust load, the A's in the equations should be replaced by B's and vice versa.

For two-row similar bearing series with no external thrust, F_{ae}=0, the dynamic equivalent radial load, P, equals F_{rAB} or F_{rC}. Since F_{rAB} or F_{rc} is the radial load on the two-row assembly, the two-row basic dynamic radial loads rating, $C_{90(2)}$, is to be used to calculate bearing life.

Design	Thrust Condition	Dynamic Equivalent Radial Load
SIMILAR BEARING SERIES, $K_A = K_B$ 	$F_{ae} \leq \dfrac{0.6\ F_{rAB}}{K_A}$	$P_A = 0.5\ F_{rAB} + 0.83\ K_A\ F_{ae}$ $P_B = 0.5\ F_{rAB} - 0.83\ K_A\ F_{ae}$
	$F_{ae} > \dfrac{0.6\ F_{rAB}}{K_A}$	$P_A = 0.4\ F_{rAB} + K_A\ F_{ae}$ $P_B = 0$

Design	Thrust Condition	Dynamic Equivalent Radial Load
DISSIMILAR BEARING SERIES, $K_A \neq K_B$ 	$F_{ae} \leq \dfrac{0.6\ F_{rAB}}{K_A}$	$P_A = \dfrac{K_A}{K_A + K_B}\ (F_{rAB} + 1.67\ K_B\ F_{ae})$ $P_B = \dfrac{K_B}{K_A + K_B}\ (F_{rAB} - 1.67\ K_A\ F_{ae})$
	$F_{ae} > \dfrac{0.6\ F_{rAB}}{K_A}$	$P_A = 0.4\ F_{rAB} + K_A\ F_{ae}$ $P_B = 0$

Note: F_{rAB} is the radial load on the two-row assembly. The single-row basic dynamic radial load rating, C_{90}, is to be applied when calculating life based on the above equations.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

OPTIONAL APPROACH FOR DETERMINING DYNAMIC EQUIVALENT RADIAL LOADS

The following is a general approach to determining the dynamic equivalent radial loads. Here, a factor "m" has to be defined as +1 for direct-mounted single-row or two-row bearings or −1 for indirect mounted bearings. Also a sign convention is necessary for the external thrust F_{ae} as follows:

a. In case of external thrust applied to the shaft (typical rotating cone application), F_{ae} to the right is positive; to the left is negative.

b. When external thrust is applied to the housing (typical rotating cup application) F_{ae} to the right is negative; to the left is positive.

1. SINGLE-ROW MOUNTING

Design	Thrust Condition	Thrust Load	Dynamic Equivalent Radial Load
Indirect Mounting (m=−1) Bearing A Bearing B $-F_{ae}$ ⟵⟶ $+F_{ae}$ F_{rA} F_{rB}	$\dfrac{0.47\ F_{rA}}{K_A} \leq \dfrac{0.47\ F_{rB}}{K_B} - m\ F_{ae}$	$F_{aA} = \dfrac{0.47\ F_{rB}}{K_B} - m\ F_{ae}$ $F_{aB} = \dfrac{0.47\ F_{rB}}{K_B}$	$P_A = 0.4\ F_{rA} + K_A\ F_{aA}$ $P_B = F_{rB}$
Direct Mounting (m=1) Bearing A Bearing B $-F_{ae}$ ⟵⟶ $+F_{ae}$ F_{rA} F_{rB}	$\dfrac{0.47\ F_{rA}}{K_A} > \dfrac{0.47\ F_{rB}}{K_B} - m\ F_{ae}$	$F_{aA} = \dfrac{0.47\ F_{rA}}{K_A}$ $F_{aB} = \dfrac{0.47\ F_{rA}}{K_A} + m\ F_{ae}$	$P_A = F_{rA}$ $P_B = 0.4\ F_{rB} + K_B\ F_{aB}$

Note: If $P_A < F_{rA}$, use $P_A = F_{rA}$ or if $P_B < F_{rB}$, use $P_B = F_{rB}$

2. TWO-ROW MOUNTING – FIXED BEARING WITH EXTERNAL THRUST, F_{ae} (SIMILAR OR DISSIMILAR SERIES)

Design	Thrust Condition	Dynamic Equivalent Radial Load
F_{rAB} Bearing A Bearing B $-F_{ae}$ ⟵⟶ $+F_{ae}$ Fixed Bearing Indirect Mounting (m=−1)	$F_{ae} \leq \dfrac{0.6\ F_{rAB}}{K^*}$	$P_A = \dfrac{K_A}{K_A + K_B}\ (F_{rAB} - 1.67\ m\ K_B\ F_{ae})$ $P_B = \dfrac{K_B}{K_A + K_B}\ (F_{rAB} + 1.67\ m\ K_A\ F_{ae})$
F_{rAB} Bearing A Bearing B $-F_{ae}$ ⟵⟶ $+F_{ae}$ Fixed Bearing Direct Mounting (m=1)	$F_{ae} > \dfrac{0.6\ F_{rAB}}{K^*}$	$P_A = 0.4\ F_{rAB} - m\ K_A\ F_{ae}$ $P_B = 0.4\ F_{rAB} + m\ K_B\ F_{ae}$

Note: F_{rAB} is the radial load on the two-row assembly. The single-row basic dynamic radial load rating, C_{90}, is to be applied when calculating life based on the above equations.

A

When the loading is static, it is usually suggested that the applied load be no greater than the basic static load rating divided by the appropriate factor (HF_s) as shown in the table below.

Hardness Factors to Modify BASIC STATIC LOAD RATING	
Raceway Hardness HRC	Hardness Factor HF_s
58	1.00
57	1.06
56	1.13
55	1.21

43	2.57
42	2.74
41	2.92
40	3.10

MINIMUM BEARING LOAD

Slippage can occur if loads are too light and, if accompanied by inadequate lubrication, cause damage to the bearings. The minimum load for radial cylindrical, spherical and full-complement needle roller bearings is $P/C = 0.04$ (P is the dynamic load and C is the basic dynamic load rating).

Thrust needle roller bearings also have an added design requirement such that the minimum thrust load is satisfied to prevent the rollers from skidding on the raceway. (The equation for the thrust loading force is different for needle rollers versus cylindrical rollers as noted):

(needle rollers) $F_{a\,min} = C_0/2200$ kN
(cylindrical rollers) $F_{a\,min} = 0.1C_0/2200$ kN

Centrifugal force in thrust spherical roller bearings tends to propel the rollers outward. The bearing geometry converts this force to another induced thrust component which must be overcome by an axial load. This induced thrust (F_{ac}) is given by:

$$F_{ac} = kn^2 \times 10^{-5} \quad \text{(lbf)}$$

The minimum required working thrust load on a thrust spherical roller bearing ($F_{a\,min}$) is then computed by:

$$F_{a\,min} = 1.2\,F_r + F_{ac} \geq \frac{C_{0a}}{1000} \quad \text{(lbf)}$$

In addition to meeting the above calculated value, the minimum required working thrust load ($F_{a\,min}$) should be equal to or greater than 0.1 percent of the static thrust load rating (C_{0a}).

CYLINDRICAL ROLLER BEARING MAXIMUM ALLOWABLE AXIAL LOAD

Metric series cylindrical roller bearings of NUP, NP, NF, as well as NU or NJ designs with a thrust collar, can transmit axial loads if they are radially loaded at the same time. The allowable axial load ratio F_a/C of 0.1 maximum depends to a great extent on the magnitude of radial load, the operating speed, type of lubricant used, the operating temperature, and heat transfer conditions at the bearing location. The heat balance achieved at the bearing location is used as a basis for determination of the allowable axial load.

The nomogram on page A35 should be used to determine the allowable axial load F_{az} based on the following operating conditions:
- The axial load is of constant direction and magnitude
- Radial load ratio $F_r/C \leq 0.2$
- Ratio of axial load to radial load $F_a/F_r < 0.4$
- The temperature of the bearing is 80° C (176° F) at an ambient temperature of 20° C (68° F).
- Lubricating oil is ISO VG 100 or greater using oil bath lubrication or circulating oil.
- As an alternative, the bearing may be lubricated with a grease using the above specified base oil and viscosity. Use of EP additives will be necessary, although considerably shorter relubrication intervals may be expected than with purely radially loaded radial cylindrical roller bearings.

Example of using the nomogram

From the lower part of the nomogram, determine the intersection point of the inner ring bore diameter and the dimension series of the bearing. From the upper part, the allowable axial load ratio F_{az}/C can be found as a function of the operating speed, n.

For a cylindrical roller radial bearing NU2207E.TVP
C = 63 kN; d = 35 mm
n = 2000 RPM
F_r = 10 kN

From the nomogram:
$F_{az}/C = 0.06$
Then $F_{az} = 0.06 \cdot 63$
The calculated allowable axial load F_{az} is 3.78 kN

It should be noted that an axial load as high as that determined by means of the nomogram should not be applied if an oil of rated kinematic viscosity lower than ISO VG 100 is used. Suitable EP additives, which are known for fatigue life improving qualities, may allow for an increase in applied axial load subject to thorough testing.

Higher applied axial loads

Axial loads greater than those determined by means of the nomogram may be considered, providing they are to be applied intermittently. Also, the bearing should be cooled using circulating oil lubrication and if the operating temperature, due to the internal friction and the higher axial load, exceeds 80° C (176° F), a more viscous oil must be used.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

Operating speed n
The basic dynamic load rating and the static load rating are commonly used for bearing selection. The basic dynamic load rating is used to estimate life of a rotating bearing. Static load ratings are used to determine the maximum permissible load that can be applied to a non-rotating bearing.

The basic philosophy of The Timken Company is to provide the most realistic bearing rating to assist our customers in the bearing selection process. Published ratings for Timken bearings include the basic dynamic radial load rating C. This value is based on a basic rating life of one million revolutions. Timken tapered roller bearings also include the basic dynamic load rating C_{90}, which is based on rating life of ninety million revolutions. The basic static radial load rating is C_o.

Static load rating

The basic static radial load rating and thrust load rating for Timken bearings are based on a maximum contact stress within a non-rotating bearing of 4000 MPa (580 ksi) for roller bearings and 4200 MPa (607 ksi) for ball bearings, at the center of contact on the most heavily loaded rolling element.

The 4000 MPa (580 ksi) or 4200 MPa (607 ksi) stress levels may cause visible light brinell marks on the bearing raceways. This degree of marking will not have a measurable effect on fatigue life when the bearing is subsequently rotating under a lower application load. If sound, vibration or torque are critical, or if a pronounced shock load is present, a lower load limit should be applied. For more information on selecting a bearing for static load conditions, consult your Timken representative.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

STATIC RADIAL AND/OR AXIAL EQUIVALENT LOADS

The static equivalent radial and/or axial loading is dependent on the bearing type selected. For bearings designed to accommodate only radial or thrust loading, the static equivalent load is equivalent to the applied load.

For all bearings, the maximum contact stress can be approximated using the static equivalent load and the static rating.

For roller bearings:

$$\sigma_0 = 4000 \cdot \left(\frac{P_0}{C_0} \right)^{1/2} \text{ MPa}$$

$$\sigma_0 = 580 \cdot \left(\frac{P_0}{C_0} \right)^{1/2} \text{ ksi}$$

For ball bearings:

$$\sigma_0 = 4200 \cdot \left(\frac{P_0}{C_0} \right)^{1/3} \text{ MPa}$$

$$\sigma_0 = 607 \cdot \left(\frac{P_0}{C_0} \right)^{1/3} \text{ ksi}$$

Radial ball bearings

The dynamic equivalent radial load is used for comparison with the static load rating. Refer to the Dynamic Equivalent Radial and/or Axial Loads section.

Thrust ball bearings

Similar to radial ball bearings, thrust ball bearings use the same equation for equivalent static and dynamic loading.

$$P_{0a} = X \cdot F_r + Y \cdot F_a$$

The X and Y factors are listed in the bearing tables along with the minimum required thrust load-to-radial load ratio for maintaining proper operation.

Radial spherical roller bearings

The load factors X_0 and Y_0, which are listed in the bearing tables, are used with the following equation to estimate the static radial equivalent load.

$$P_{0r} = X_0 \cdot F_r + Y_0 \cdot F_a$$

Thrust spherical roller bearings

The following equation is used for thrust spherical roller bearings.

$$P_{0a} = F_a + 2.7 \, F_r$$

Thrust spherical roller bearings require a minimum thrust load for proper operation. $P_{oa} =$ should not be greater than 0.5 C_{oa}. If conditions exceed this, consult your Timken representative.

Tapered roller bearings

To determine the static equivalent radial load for a single-row mounting, first determine the thrust load, (F_a), then use the equations in this section, depending on the appropriate thrust load condition.

Needle roller bearings

Because radial needle roller bearings are not designed to accept thrust loading, their equation to determine static radial equivalent load is:

$$P_{0r} = F_r$$

Thrust needle roller bearings are not designed to accept radial loading, so their equation to determine static thrust equivalent load is:

$$P_{0a} = F_a$$

Static equivalent radial load (two-row bearings)

The bearing data tables do not include static rating for two-row bearings. The two-row static radial rating can be estimated as:

$$C_{o(2)} = 2C_o$$

where:

$C_{o(2)}$ = two-row static radial rating
C_o = static radial load rating of a single row bearing, type TS, from the same series

Thrust Condition	Net Bearing Thrust Load	Static Equivalent Radial Load (P_0)	
$\dfrac{0.47 \, F_{rA}}{K_A} \leq \dfrac{0.47 \, F_{rB}}{K_B} + F_{ae}$	$F_{aA} = \dfrac{0.47 \, F_{rB}}{K_B} + F_{ae}$ $F_{aB} = \dfrac{0.47 \, F_{rB}}{K_B}$	$P_{0B} = F_{rB}$ for $F_{aA} < 0.6 \, F_{rA} / K_A$ $P_{0A} = 1.6 \, F_{rA} - 1.269 \, K_A \, F_{aA}$ for $F_{aA} > 0.6 \, F_{rA} / K_A$ $P_{0A} = 0.5 \, F_{rA} + 0.564 \, K_A \, F_{aA}$	Please refer to illustrations on page A169.
$\dfrac{0.47 \, F_{rA}}{K_A} > \dfrac{0.47 \, F_{rB}}{K_B} + F_{ae}$	$F_{aA} = \dfrac{0.47 \, F_{rA}}{K_A}$ $F_{aB} = \dfrac{0.47 \, F_{rA}}{K_A} - F_{ae}$	for $F_{aB} > 0.6 \, F_{rB} / K_B$ $P_{0B} = 0.5 \, F_{rB} + 0.564 \, K_B \, F_{aB}$ for $F_{aB} < 0.6 \, F_{rB} / K_B$ $P_{0B} = 1.6 \, F_{rB} - 1.269 \, K_B \, F_{aB}$ $P_{0A} = F_{rA}$	

where:

F_r = applied radial load
F_a = net bearing thrust load. F_{aA} and F_{aB} calculated from equations.

Note: Use the values of P_0 calculated for comparison with the static rating, C_o, even if P_0 is less than the radial applied, F_r.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

BEARING LIFE

Many different performance criteria exist that dictate how a bearing should be selected. These include bearing fatigue life, rotational precision, power requirements, temperature limits, speed capabilities, sound, etc. This publication deals primarily with bearing life as related to material associated fatigue. Bearing life is defined here as the length of time, or number of revolutions, until a fatigue spall of 6 mm^2 (0.01 in.^{2}) develops. Since metal fatigue is a statistical phenomenon, the life of an individual bearing is impossible to precisely predetermine. Bearings that may appear to be identical can exhibit considerable life scatter when tested under identical conditions. Thus it is necessary to base life predictions on a statistical evaluation of a large number of bearings operating under similar conditions. The Weibull distribution function is commonly used to predict the life of a population of bearings at any given reliability level.

RATING LIFE

Rating life, (L_{10}), is the life that 90 percent of a group of apparently identical bearings will complete or exceed before a fatigue spall develops. The L_{10} life also is associated with 90 percent reliability for a single bearing under a certain load.

BEARING LIFE EQUATIONS

Traditionally, the L_{10} life has been calculated as follows for bearings under radial or combined loading where the dynamic equivalent radial load, (P_r), has been determined:

$$L_{10} = \left(\frac{C}{P_r}\right)^e (1 \times 10^6) \text{ revolutions}$$

or,

$$L_{10} = \left(\frac{C}{P_r}\right)^e \left(\frac{1 \times 10^6}{60n}\right) \text{ hours}$$

For thrust bearings, the above equations change to the following.

$$L_{10} = \left(\frac{C_a}{P_a}\right)^e (1 \times 10^6) \text{ revolutions}$$

or,

$$L_{10} = \left(\frac{C_a}{P_a}\right)^e \left(\frac{1 \times 10^6}{60n}\right) \text{ hours}$$

$e = 3$ for ball bearings
   $= {}^{10}/_3$ for roller bearings

Tapered roller bearings often use a dynamic load rating based on ninety million cycles, as opposed to one million cycles, changing the equations as follows.

$$L_{10} = \left(\frac{C_{90}}{P_r}\right)^{10/3} (90 \times 10^6) \text{ revolutions}$$

or,

$$L_{10} = \left(\frac{C_{90}}{P_r}\right)^{10/3} \left(\frac{90 \times 10^6}{60n}\right) \text{ hours}$$

and

$$L_{10} = \left(\frac{C_{90a}}{P_a}\right)^{10/3} (90 \times 10^6) \text{ revolutions}$$

or,

$$L_{10} = \left(\frac{C_{90a}}{P_a}\right)^{10/3} \left(\frac{90 \times 10^6}{60n}\right) \text{ hours}$$

As the first set of equations for radial bearings with dynamic ratings based on one million revolutions is the most common form of the equations, this will be used through the rest of this section. The equivalent dynamic load equations and the life adjustment factors are applicable to all forms of the life equation.

With increased emphasis on the relationship between the reference conditions and the actual environment in which the bearing operates in the machine, the traditional life equations have been expanded to include certain additional variables that affect bearing performance. The approach whereby these factors, including a factor for useful life, are considered in the bearing analysis and selection, has been termed Bearing Systems Analysis (BSA).

The ISO/ABMA expanded bearing life equation is:

$$L_{10a} = a_1 a_2 a_3 L_{10}$$

Where,

   $a_1 =$ Reliability Life Factor
   $a_2 =$ Material Life Factor
   $a_3 =$ Operating Condition Life Factor
      (to be specified by the manufacturer)

The Timken expanded bearing life equation is:

$$L_{10a} = a_1 a_2 a_{3d} a_{3h} a_{3k} a_{3l} a_{3m} a_{3p} \left(\frac{C}{F_r}\right)^e (1 \times 10^6)$$

Where,

   a_1 = Reliability Life Factor
   a_2 = Material Life Factor
   a_{3d} = Debris Life Factor
   a_{3h} = Hardness Life Factor
   a_{3k} = Load Zone Life Factor
   a_{3l} = Lubrication Life Factor
   a_{3m} = Misalignment Life Factor
   a_{3p} = Low Load Life Factor

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

Reliability Life Factor (a_1)

The equation for the life adjustment factor for reliability is:

$$a_1 = 4.26 \cdot \left(\ln \frac{100}{R} \right)^{2/3} + 0.05$$

ln = natural logarithm (base e)

To adjust the calculated L_{10} life for reliability, multiply by the a_1 factor. If 90 (90 percent reliability) is substituted for R in the above equation, $a_1 = 1$. For R = 99 (99 percent reliability), $a_1 = 0.25$. The following table lists the reliability factor for commonly used reliability values.

R (percent)	L_n	a1
90	L_{10}	1.00
95	L_5	0.64
96	L_4	0.55
97	L_3	0.47
98	L_2	0.37
99	L_1	0.25
99.5	$L_{0.5}$	0.175
99.9	$L_{0.1}$	0.093

Note that the equation for reliability adjustment assumes there is a short minimum life below which the probability of bearing damage is minimal (e.g., zero probability of bearing damage producing a short life). Extensive bearing fatigue life testing has shown the minimum life, below which the probability of bearing damage is negligible, to be larger than shown above. For a more accurate prediction of bearing lives at high levels of reliability, consult your Timken representative.

Material Life Factor (a_2)

The life adjustment factor for bearing material, (a_2), for standard Timken bearings manufactured from bearing quality steel is 1.0. Bearings also are manufactured from premium steels, containing fewer and smaller inclusion impurities than standard steels and providing the benefit of extending bearing fatigue life (e.g., DuraSpexx™). Application of the material life factor requires that fatigue life is limited by nonmetallic inclusions, that contact stresses are approximately less than 2400 MPa (350 ksi), and adequate lubrication is provided. It is important to note that improvements in material cannot offset poor lubrication in an operating bearing system. Consult your Timken representative for applicability of the material factor.

Debris Life Factor (a_{3d})

Debris within a lubrication system reduces the life of a roller bearing by creating indentations on the contacting surfaces, leading to stress risers. The Timken life rating equations were developed based on test data obtained with 40 µm oil filtration, and measured ISO cleanliness levels of approximately 15/12, which is typical of cleanliness levels found in normal industrial machinery. When more or less debris is present within the system, the fatigue life predictions can be adjusted according to the measured or expected ISO lubricant cleanliness level to more accurately reflect the expected bearing performance.

As opposed to determining the debris life factor based on filtration and ISO cleanliness levels, a Debris Signature Analysis™ can be performed for more accurate bearing performance predictions. The Debris Signature Analysis is a process for determining the effects of the actual debris present in your system on the bearing performance. The typical way in which this occurs is through measurements of dented/bruised surfaces on actual bearings run in a given application. This type of analysis can be beneficial because different types of debris cause differing levels of performance, even when they are of the same size and amount in the lubricant. Soft, ductile particles can cause less performance degradation than hard, brittle particles. Hard, ductile particles are typically most detrimental to bearing life. Brittle particles can break down, thus not affecting performance to as large of a degree as hard ductile particles. For more information on Debris Signature Analysis or the availability of Debris Resistant bearings for your application, consult your Timken representative.
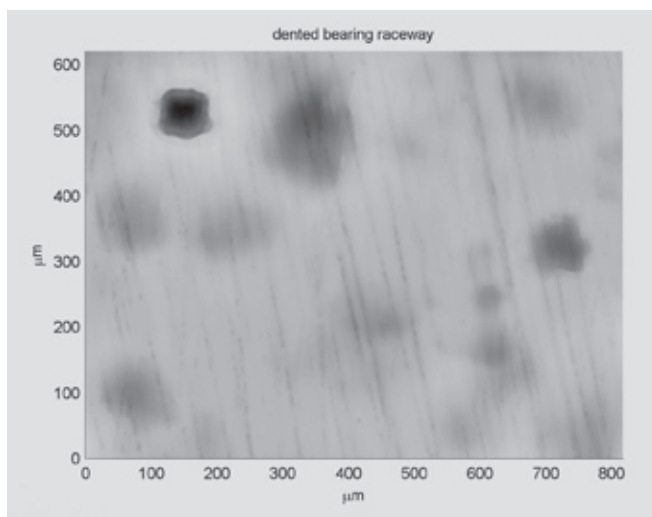

Surface map of a bearing raceway with debris denting.

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

Hardness Life Factor (a$_{3h}$)

Both the dynamic and static load ratings of Timken bearings are based on a minimum raceway hardness equivalent to 58 on the Rockwell C scale (HRC) [ASTM E-18]. If the raceway hardness must be decreased, these load ratings also will be decreased. For Timken bearings supplied as a full assembly, the hardness life factor will be unity. For bearing applications designed to use the shaft or housing surfaces as raceways, this factor can be used to estimate performance when the required 58 HRC minimum hardness cannot be achieved.

The effective raceway hardness affects the life of a bearing application as shown in the following table. If values for raceway hardness below 45 HRC are required, consult your Timken representative.

Raceway Hardness (HRC)	a$_{3h}$
58	1.00
57	0.81
56	0.66
55	0.53
54	0.43
53	0.35
52	0.28
51	0.22
50	0.18
49	0.14
48	0.11
47	0.09
46	0.07
45	0.06

Load Zone Life Factor (a$_{3k}$)

The fatigue life of a bearing is a function of the stresses in rollers and raceways and the number of stress cycles that the loaded bearing surfaces experience in one bearing revolution. The stresses depend on applied load and on how many rollers support that load. The number of stress cycles depends on bearing geometry and, again, on how many rollers support the load. Therefore, life for a given external load is related to the loaded arc, or load zone, of the bearing.

The load zone in a bearing is dominated by the internal clearance, either radial or axial depending on the bearing type. Neglecting preload, less clearance in a bearing results in a larger load zone and subsequently longer bearing life.
Bearing Load Zones and Roller-Raceway Contact Loading.

Using the dynamic equivalent load (Pr) instead of the applied radial load (Fr) in the equation for L$_{10a}$ roughly approximates the load zone factor for combined loading only. If a more accurate assessment of the load zone adjusted life is necessary (e.g., including the effects of internal clearance or fitting practice), consult your Timken representative.

Lubrication Life Factor (a$_{3l}$)

The influence of lubrication film due to elastohydrodynamic (EHL) lubrication on bearing performance is related to the reduction or prevention of asperity (metal-metal) contact between the bearing surfaces. Extensive testing has been done at Timken Research to quantify the effects of the lubrication related parameters on bearing life. It has been found that the roller and raceway surface finish, relative to lubricant film thickness, has the most notable effect on improving bearing performance. Factors such as bearing geometry, material, loads and load zones also play an important role in bearing performance.

The following equation provides a method to calculate the lubrication factor for a more accurate prediction of the influence of lubrication on bearing life (L$_{10a}$).

$$a_{3l} = C_g \cdot C_l \cdot C_j \cdot C_s \cdot C_v \cdot C_{gr}$$

Where:

C_g = geometry factor
C_l = load factor
C_j = load zone factor
C_s = speed factor
C_v = viscosity factor
C_{gr} = grease lubrication factor

Note: The a$_{3l}$ maximum is 2.88 for all bearings. The a$_{3l}$ minimum is 0.200 for case carburized bearings and 0.126 for through hardened bearings.

A lubricant contamination factor is not included in the lubrication factor because Timken endurance tests are typically run with a 40 μm filter to provide a realistic level of lubricant cleanness for most applications.

Geometry factor - C$_g$

C_g is given for most part numbers in the bearing tables. The geometry factor also includes the material effects and load zone considerations for non-tapered roller bearings, as these also are inherent to the bearing design. However, it should be noted that the primary effect of the load zone is on roller load distributions and contact stresses within the bearing, which are not quantified within the lubrication factor. Refer to the previous section Load Zone Life Factor (a$_{3k}$) for more information.

Note that the geometry factor (C$_g$) factor is not applicable to our DuraSpexx™ product. For more information on our DuraSpexx™ product, consult your Timken representative.

A

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

Load factor - C_l

The C_l factor is obtained from the following figure. Note that the factor is different based on the type of bearing utilized. P_r is the equivalent load applied to the bearing in Newtons and is determined in the Equivalent Bearing Loads (P_r) section.

LOAD FACTOR (C_l) VS. EQUIVALENT BEARING LOAD (P_r)

P_r (newtons)
(F_a for single-row tapered roller bearings)
Load zone factor - C_j

As mentioned previously, for all non-tapered roller bearings the load zone factor is unity. For tapered roller bearings, the load zone factor can be taken from the graph based on the thrust load applied to that bearing.

LOAD ZONE FACTOR (C_j) VS. TAPERED BEARING THRUST LOAD (F_a)

$\dfrac{F_r}{F_a K}$
Speed factor - C_s

C_s is determined from the following figure, where rev/min (RPM) is the rotational speed of the inner ring relative to the outer ring.

SPEED FACTOR (C_s) VS. ROTATIONAL SPEED

Rotational Speed (RPM)
Viscosity factor - C_v

The lubricant kinematic viscosity [centistokes (cSt)] is taken at the operating temperature of the bearing. The operating viscosity can be estimated by using the figure in the Speed, Heat and Torque section. The viscosity factor (C_v) can then be determined from the following figure.

VISCOSITY FACTOR (C_v) VS. KINEMATIC VISCOSITY

Kinematic Viscosity (cSt)
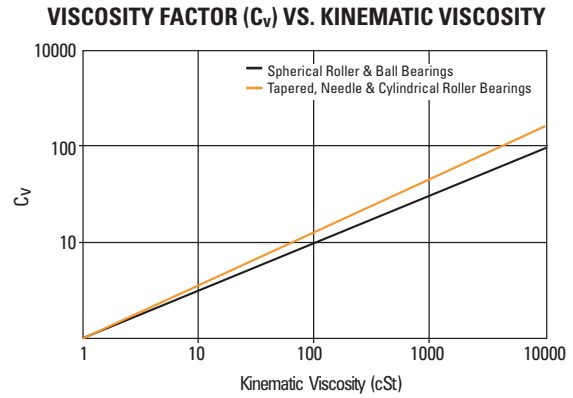

Grease lubrication factor – C_{gr}

For grease lubrication, the EHL lubrication film becomes depleted of oil over time and is reduced in thickness. Consequently, a reduction factor (C_{gr}) should be used to adjust for this effect.

$C_{gr} = 0.79$

● ●

Misalignment life factor (a_{3m})

The effect of bearing life depends on the magnitude of the angle of misalignment, on the internal bearing geometry, and on the applied loads.

The misalignment life factor for spherical bearings is equal to one, $a_{3m}=1$, due to the self-aligning capabilities of a spherical roller bearing. The allowable misalignment in a spherical roller bearing is between 1 degree and 2.5 degrees, depending upon the series of the bearing as detailed in the following table. Life will be reduced if these limits are exceeded, due to roller-raceway contact truncation.

MAXIMUM PERMISSIBLE MISALIGNMENTS FOR SPHERICAL ROLLER BEARINGS BASED ON SERIES

Bearing Series	Maximum Misalignment
238	±1.0°
222, 230, 231, 239, 249	±1.5°
223, 240	±2.0°
232, 241	±2.5°

BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

For needle roller bearings, the following table gives the misalignment limitations based on bearing width.

Bearing Width		Maximum Slope	
mm	inches	Caged	Full Complement
> 50	> 2	0.0005	0.0005
25-50	1-2	0.0010	0.0005
< 25	< 1	0.0015	0.0010

For all other bearing types, accurate alignment of the shaft relative to the housing is critical for best performance. The life prediction using the method defined in this publication is relatively accurate up to the limits listed within, based on bearing type. The base condition for which the load rating of the roller bearings are defined is 0.0005 radians misalignment.

For cylindrical roller bearings, the misalignment factor also is a measure of the effect of bearing axial load on life. Axial loading of the bearing causes a moment to be generated about the roller center, thus shifting the roller-raceway contact stresses toward the end of the roller, similar to bearing misalignment.

Performance of all Timken bearings under various levels of misalignment, radial and axial load can be predicted using sophisticated computer programs. Using these programs, Timken engineers can design special bearing contact profiles to accommodate the conditions of radial load, axial load and/or bearing misalignment in your application. Consult your Timken representative for more information.
Roller-inner raceway contact stress without misalignment.
Roller-inner raceway contact stress with high misalignment and special profile.

Needle rollers with relieved ends

Needle roller bearing life is affected by the distribution of contact stress between roller and raceways. Even when non-profiled needle rollers are loaded under conditions of ideal alignment, the contact stress is not uniform along the length of the rollers, but rather is concentrated towards the ends. Misalignment causes even greater roller contact stress. This effect is illustrated below.

Needle Roller – Cylindrical   Needle Roller- Relieved Ends (exaggerated for clarity)
Fig. A-11
Comparative Stress Patterns

The use of needle rollers with relieved ends helps to reduce stress concentration at the ends of rollers, both under misalignment or ideal alignment, and results in more uniform stress distribution and optimum bearings performance.

Low load life factor (a$_{3p}$)

Bearing life tests at the Timken Technology Center have shown greatly extended bearing fatigue life performance is achievable when the bearing contact stresses are low and the lubricant film is sufficient to fully separate the micro-scale textures of the contacting surfaces. Mating the test data with sophisticated computer programs for predicting bearing performance, Timken engineers have developed a low load factor for use in the catalog to predict the life increase expected when operating under low bearing loads. The following figure shows the low load factor (a$_{3p}$) as a function of the lubricant life factor (a$_{3l}$) and the ratio of bearing dynamic rating to the bearing equivalent load.

LOW LOAD FACTOR (a$_{3P}$) VS. LUBRICANT LIFE FACTOR (a$_{3L}$) AND C$_{90}$/P$_R$ RATIO.

A
BEARING REACTIONS, DYNAMIC EQUIVALENT LOADS & BEARING LIFE - *continued*

LIFE - THRUST SPHERICAL, CYLINDRICAL AND TAPERED ROLLER BEARINGS

The life formula, below , is the radial roller bearing life equation restated in terms of thrust instead of radial ratings and radial equivalent loads.

$$L_{10} = \frac{16667}{n} \left[\frac{C_t}{T_e} \right]^{10/3} \text{(Hours)}$$

The calculations of bearing life may also be performed by using logarithmic factors for rotational speed (N_f) and life (L_f) based on the formula:

$$L_{10} = 500 \, (L_f)^{10/3} \text{ (Hours)}$$

where $L_f = \left[\dfrac{C_t \, n_f}{T_e} \right]$

where $N_f = \left[\dfrac{1}{.03n} \right]^{3/10}$

Referring back to the above equation it may be advisable, as previously noted with radial bearings, under certain operating conditions to include an application factor a_3 and calculate life according to the formula:

$$L_{10} = \frac{16667}{n} \, a_3 \left[\frac{C_t}{T_e} \right]^{10/3} \text{ or } L_{10} = 500 \, a_3 \, (L_f)^{10/3} \text{(Hours)}$$

a_3 is the factor based on application conditions. Under optimum conditions $a_3 = 1$. Depending on lubricant contamination, temperatures, impact loading and load reversals a3 may be less than 1 and as low as 0.05. Consult your Timken representative for assistance with your specific application requirements.

LIFE - THRUST BALL BEARINGS

$$L_{10} = \frac{16667}{n} \left[\frac{C_t}{T_e} \right]^{3} \text{(Hours)}$$

It may be advisable under certain operating conditions to include an application factor a_3 and calculate life according to the formula:

$$L_{10} = \frac{16667}{n} \, a_3 \left[\frac{C_t}{T_e} \right]^{3} \text{(Hours)}$$

a_3, the life factor based on application conditions, can be assigned values as described above.

BEARING TOLERANCES, INCH & METRIC

A

TOLERANCES

Standards defining practices for ball and roller bearing usage are listed in the following tables. These standards are provided for use in selecting bearings for general applications in conjunction with the bearing mounting and fitting practices offered in later sections.

RADIAL BALL, SPHERICAL AND CYLINDRICAL ROLLER BEARINGS

Depending on your specific application requirements, various degrees of bearing accuracy may be required.

Timken maintains ball diameter and sphericity tolerances, close control of race contours and internal clearances, accuracy of cage construction, and unusually fine surface finishes.

The tolerances in this table are in conformance with ANSI ABMA Standard 20 - 1987.

ABMA / ISO Symbols - Inner Ring

Δ_dmp — Single plane mean bore diameter deviation from basic bore diameter, e.g., bore tolerance for a basically tapered bore, Δ_dmp refers only to the theoretical small bore end of the bore

K_ia — Radial runout of assembled bearing inner ring, e.g., radial runout of raceway

V_Bs — Inner ring width variation, e.g., parallelism

S_d — Inner ring reference face runout with bore, e.g., squareness - bore to face

S_ia — Axial runout of assembled bearing inner ring, e.g., lateral (axial) runout of raceway

Δ_Bs — Single inner ring width deviation from basic, e.g., width tolerance

ABMA / ISO Symbols - Outer Ring

Δ_Dmp — Single plane mean outside diameter deviation from basic outside diameter, e.g., O.D. tolerance

K_ea — Radial runout of assembled bearing outer ring, e.g., radial runout of raceway

V_Cs — Outer ring width variation, e.g., parallelism

S_D — Outside cylindrical surface runout with outer ring reference face, e.g., squareness O.D. to face

S_ea — Axial runout of assembled bearing outer ring, e.g., lateral (axial) runout of raceway

Δ_Cs — Outer ring width deviation from basic, e.g., width tolerance

BEARING TOLERANCES, INCH & METRIC - *continued*

These standards, coupled with proprietary design, material and processing specifications, ensure that our bearings offer the maximum performance.

Among the tolerance classes, ABEC 1 applies to ball bearings for normal usage. The other classes ABEC 3, 5, 7, 9 apply to ball bearings of increased precision as required. RBEC 1 applies to roller bearings for normal usage. RBEC 3 and 5 apply to roller bearings of increased precision as required.

TOLERANCE TERMS, SYMBOLS AND DEFINITIONS
Axes, planes etc.

Inner ring (or shaft washer) axis: Axis of the cylinder inscribed in a basically cylindrical bore. The inner ring (or shaft washer) axis is also the bearing axis.

Outer ring (or housing washer) axis: Axis of the cylinder circumscribed around a basically cylindrical outside surface.

Radial plane: Plane perpendicular to the bearing or ring axis. It is, however, acceptable to consider radial planes referred to in the definitions as being parallel with the plane tangential to the reference face of a ring or the back face of a thrust bearing washer.

Radial direction: Direction through the bearing or ring axis in a radial plane.

Axial plane: Plane containing the bearing or ring axis.

Axial direction: Direction parallel with the bearing or ring axis. It is, however, acceptable to consider axial directions referred to in the definitions as being perpendicular to the plane tangential to the reference face of a ring or back face of a thrust bearing washer.

Reference face: Face designated by the manufacturer of the bearings, and which may be the datum for measurements.

NOTE: The reference face for measurement is generally taken as the unmarked face. In case of symmetrical rings when it is not possible to identify the reference face, the tolerances are deemed to comply relative to either face, but not both. The reference face of a shaft and housing washer as a thrust bearing is that face intended to support axial load and is generally opposite the raceway face.

Outer ring flange back face: That side of an outer ring flange which is intended to support axial load.

Middle of raceway: Point or line on a raceway surface, halfway between the two edges of the raceway.

Raceway contact diameter: Diameter of the theoretical circle through the nominal points of contact between the rolling elements and raceway.

NOTE: For roller bearings, the nominal point of contact is generally at the middle of the roller.

Diameter deviation near ring faces: In radial planes, nearer the face of a ring than 1.2 times the maximum (axial direction) ring chamfer, only the maximum material limits apply.
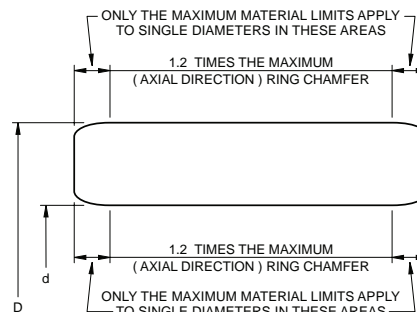

ONLY THE MAXIMUM MATERIAL LIMITS APPLY TO SINGLE DIAMETERS IN THESE AREAS

1.2 TIMES THE MAXIMUM (AXIAL DIRECTION) RING CHAMFER

1.2 TIMES THE MAXIMUM (AXIAL DIRECTION) RING CHAMFER

ONLY THE MAXIMUM MATERIAL LIMITS APPLY TO SINGLE DIAMETERS IN THESE AREAS

ABMA / ISO Symbols - Inner Ring

Δ_{dmp} — Single plane mean bore diameter deviation from basic bore diameter, e.g., bore tolerance for a basically tapered bore, Δ_{dmp} refers only to the theoretical small bore end of the bore.

V_{dsp} — Difference between the largest and the smallest of the single bore diameters in a single radial plane.

V_{dmp} — Difference between the largest and smallest of the mean bore diameters in a single radial plane of an individual ring.

ABMA / ISO Symbols - Outer Ring

Δ_{Dmp} — Single plane mean outside diameter deviation from basic outside diameter, e.g., O.D. tolerance.

V_{Dsp} — Difference between the largest and smallest of the single outside diameters in a single radial plane.

A

TOLERANCES FOR NEEDLE ROLLER AND CAGE THRUST ASSEMBLIES

Tolerances for the bore diameters and outside diameters of inch thrust assemblies are given in Table 9.

TABLE 9

TOLERANCES FOR BORE (D_{C1}) AND OUTSIDE (D_C) DIAMETERS OF NOMINAL INCH (NTA) NEEDLE ROLLER AND CAGE THRUST ASSEMBLIES				
	Deviations			
Needle roller Bore Diameter (D_w)	**Diameter (D_{c1})**		**Outside Diameter (D_c)**	
(nominal)	inch		inch	
inch	low	high	high	low
0.0781	+0.002	+0.007	-0.010	-0.020
0.1250	+0.002	+0.010	-0.010	-0.025

Bore Inspection Procedure for Assembly

The bore diameter (Dc_1) of the assembly should be checked with "go" and "no go" plug gages. The "go" plug gage size is the minimum bore diameter of the assembly. The "no go" plug gage size is the maximum bore diameter of the assembly.

The assembly, under its own free weight, must fall freely from the "go" plug gage. The "no go" plug gage must not enter the bore. Where the "no go" plug gage can be forced through the bore, the assembly must not fall from the gage under its own weight.

THRUST BEARINGS

The tolerances in this table conform to ANSI/ABMA Standard 21.2.

Certain applications for Timken cylindrical roller bearings may require special precision tolerances. Timken has for many years offered two high-precision tolerance standards which augment the ABMA tolerance system. If your application requires precision beyond ABMA tolerances, consult your Timken representative about extraprecision and ultraprecision tolerances.

TOLERANCES FOR THRUST WASHERS

Tolerances for the outside diameters and bore diameters of nominal inch thrust washers are given in Tables 10 and 11.

TOLERANCES FOR NEEDLE ROLLER AND CAGE THRUST ASSEMBLIES

Pages C234 to C237 list the nominal outside diameter, bore diameter and needle roller diameter for the FNT and AXK Series of needle roller and cage thrust assemblies and also the nominal outside diameter and bore diameter of the series AS, LS, WS and GS thrust washers. Thickness tolerances for the AS and LS thrust washers are also included.

Tolerances for the outside and bore diameters of series FNT and AXK needle roller and cage thrust assemblies are given in Table 12. The needle rollers in any one assembly have a group tolerance of 2 µm.

TABLE 12

Table title: TOLERANCES FOR BORE DIAMETER (D_{C1}) AND OUTSIDE DIAMETER (D_C) OF SERIES FNT AND AXK NEEDLE ROLLER AND CAGE THRUST ASSEMBLIES

Bore inspection procedure for assembly

If an inspection of the bore diameter is desired, the bore diameter (D_{c1}) of the assembly should be checked with "go" and "no go" plug gages. The "go" plug gage size is the minimum bore diameter of the assembly. The "no go" plug gage size is the maximum bore diameter of the assembly.

The assembly, under its own weight, must fall freely from the "go" plug gage. The "no go" plug gage must not enter the bore. Where the "no go" plug gage can be forced through the bore, the assembly must not fall from the gage under its own weight.

Tolerances for thrust washers

Tolerances for the outside and bore diameters of series AS thrust washers are given in Table 13. Thickness tolerance for series AS thrust washers is +0.05 mm.

TABLE 13

Table title: TOLERANCES FOR BORE DIAMETER (d) AND OUTSIDE DIAMETER (d_1) OF SERIES LS HEAVY THRUST WASHERS.

Bore inspection procedure for series AS and LS thrust washers

If an inspection of the thrust washer bore diameter (d) is desired, it should be checked with "go" and "no go" plug gages. The "go" plug gage size is the minimum bore diameter of the thrust washer. The "no go" plug gage size is the maximum bore diameter of the thrust washer.

The thrust washer, under its own weight, must fall freely from the "go" plug gage. The "no go" plug gage must not enter the bore. Where the "no go" plug gage can be forced through the bore, the thrust washer must not fall from the gage under its own weight.

TAPERED ROLLER BEARINGS

Timken tapered roller bearings are manufactured to a number of specifications or "classes" that define tolerances on dimensions such as bore, O.D., width and runout. The Timken Company produces bearings to both inch and metric systems. The boundary dimension tolerances applicable to these two categories of bearings differ.

The major difference between the two tolerance systems is that inch bearings have historically been manufactured to positive bore and O.D. tolerances, whereas metric bearings have been manufactured to negative tolerances.

Metric system bearings (ISO and "J" prefix parts)

Timken manufactures metric system bearings to six tolerance classes. Classes K and N are often referred to as standard classes. Class N has more closely controlled bearing width tolerances than K. Classes C, B, A and AA are "precision" classes. These tolerances lie within those currently specified in ISO 492 with the exception of a small number of dimensions indicated in the tables. The differences normally have an insignificant effect on the mounting and performance of tapered roller bearings.

The following table illustrates the current ISO bearing class that corresponds approximately to each of The Timken Company metric bearing classes.

For the exact comparison, please consult your Timken representative.

BEARING TOLERANCES, INCH & METRIC - *continued*

INCH SYSTEM BEARINGS

Inch system bearings are manufactured to a number of tolerance classes. Classes 4 and 2 are often referred to as "standard" classes.

Class 2 has certain tolerances more closely controlled than class 4 and thus may be required for specific applications. Classes 3, 0, 00 and 000 are "precision" classes.

INCH BEARING TOLERANCES (µm AND 0.0001 INCH)

BEARING TOLERANCES, INCH & METRIC - *continued*
Cone Stand. Cone stand is a measure of the variation in cone raceway size and taper and roller diameter and taper which is checked by measuring the axial location of the reference surface of a master cup or other type gage with respect to the reference face of the cone.

[1] For class 2, TDI and TDIT bearings with cone bore of 101.600 to 304.800 mm (4 in. to 12 in.), the cone stand is ±102 (±40).
Cup Stand. Cup stand is a measure of the variation in cup I.D. size and taper which is checked by measuring the axial location of the reference surface of a master plug or other type gage with respect to the reference face of the cup.

MOUNTING DESIGNS

Correct bearing mounting and fitting practices are key components of proper bearing setting. Setting is the amount of clearance or interference within a mounted bearing. Bearing internal clearance is affected by the tightness of the fit to the inner and outer races. Proper bearing setting is crucial to bearing life and performance. Although clearance is required for most mounted bearings, application dependant factors include load, speed, bearing position, installation method, materials of construction, runout accuracy, thermal considerations, hoop stress, and shaft and housing design. This section provides tables and discussion to aid in selection of the proper bearing mounting and fitting procedures to optimize performance in general applications. For special applications, please consult your Timken representative for review.

RADIAL BALL BEARINGS

In the manufacture of rolling element bearings, it is standard practice to assemble rings and rolling elements with a specified internal clearance. This characteristic is necessary to absorb the effect of press fitting the bearing rings at mounting.

Internal clearance is sometimes utilized to compensate for thermal expansion of bearings, shafts and housings or to provide a contact angle in the bearing after mounting.

Internal clearance can be measured either by gaging radially or axially.

Radial measurement is accepted as the more significant characteristic for most bearing types because it is more directly related to shaft and housing fits. It also is the method prescribed by the American Bearing Manufacturers Association (ABMA). However, tapered roller bearings and duplex sets of angular contact ball bearings are usually set axially.

The radial internal clearance (RIC) of a radial contact ball bearing can be defined as the average outer ring raceway diameter minus the average inner ring raceway diameter minus twice the ball diameter.

(RIC) can be measured mechanically by moving the outer ring, horizontally as pictured in Figure A-12. The total movement of the outer ring when the balls are properly seated in the raceways determines the (RIC). Several readings should be taken using different circumferential orientations of the rings in order to get a comprehensive average reading.
Fig. A-12

The Timken Company radial clearance designations correlate with ABMA symbols as follows:

Bearing Number Prefix	ABMA Symbol	Description
H	2	Snug; slight internal clearance; sometimes used to achieve a minimum of radial or axial play in an assembly, Example: H204K
R	0	Medium; internal clearance generally satisfactory with suggested shaft and housing fits. Example: RMM204K.
P	3	Loose; considerable internal clearance required for applications involving press fits on both inner and outer rings, extra interference fits or temperature differentials. Example: P204K.
J	4	Extra Loose; large amount of internal clearance for applications involving large interference fits or temperature differentials. Example: J204K.
JJ	5	Extra-Extra Loose; extra large amount of internal clearance for applications with large temperature differential and interference fits on both rings.

ENDPLAY

Endplay is an alternate method of measuring internal clearance and is rarely used except for certain special applications. Endplay is determined by mounting the bearing, as shown in Figure A-13, with one of its rings clamped to prevent axial movement. A reversing measuring load is applied to the unclamped ring so that the resultant movement of that ring is parallel to the bearing axis. Endplay is the total movement of the unclamped ring when the load is applied first in one direction and then in the other.
Fig. A-13

When the inner and outer ring raceway curvatures are accurately known, the free endplay can readily be calculated from the values of no load radial clearance by the following formula:

$$E = \sqrt{4dR_D(K_O + K_i - 1) - R_D^2} \text{ or } \cong \sqrt{4dR_D(K_O + K_i - 1)}$$

$\left(\text{Where } R_D^2 \text{ is generally a very small value and can be omitted for most calculations without introducing undue inaccuracy.} \right)$

E = Free endplay where

K_O = outer race contour radius expressed as a decimal fraction of the ball diameter.

K_i = inner race contour radius expressed as a decimal fraction of the ball diameter

R_D = radial clearance (no load)

d = ball diameter

MOUNTING DESIGNS *- continued*

CONTACT ANGLE

The contact angle (α) is related to internal clearance as follows:

$$\alpha = \sin^{-1} \left(\frac{E}{2 (K_o + K_i - 1)d} \right)$$

The contact angle (α) may also be accurately determined in a production bearing from its pitch diameter (P.D.) and by measuring the number of revolutions (Nc) of the ball and cage assembly relative to rotation (Ni) of the inner ring under a light thrust load.

$$(N_c) = 0.5 N_i \left(1 - \frac{d}{d_m} \cos \alpha \right)$$

$$\cos \alpha = \frac{d_m}{d} \left(1 - \frac{N_c}{0.5 N_i} \right)$$

The accuracy of this method of measurement depends greatly upon the care taken in set up. Balanced weight for thrust loading, vertical turning, slow turning, many turns, minimum lubricant of low viscosity and pre-rotation are all essential for instance. The races should not be radially restrained during the contact angle measurement.

A

RADIAL SPHERICAL ROLLER BEARINGS

Timken bearing RIC allows a tight fit, with sufficient internal clearance after installation for normal operating conditions.

Spherical roller bearings with tapered bore (K) require a slightly greater interference fit on the shaft than would a cylindrical bore bearing. The effect of this greater interference fit is a reduction of RIC. For tapered bore bearings, it is critical to select the RIC that allows for this reduction.

For example, bearing number 22328K C3 (140 mm bore with C3 clearance) is to be mounted on a tapered shaft. By feeler gaging, RIC is found to be 0.178 mm (0.007 in.). The chart indicates that the proper fit will be obtained when RIC is reduced by 0.064 to 0.089 mm (0.0025 in. to 0.0035 in.). Clearance after mounting is computed: 0.178 - 0.076 = 0.102 mm (0.007 in. - 0.003 in. = 0.004 in.). The locknut should be tightened until RIC reaches 0.102 mm (0.004 in.).

Several factors influence RIC reduction. Inner rings pressed into solid steel shafts expand approximately 80 percent of the interference fit. Outer rings pressed into steel or cast iron housings reduce RIC by about 60 percent of the interference fit. For RIC reduction on hollow shafts or non-steel materials, consult your local Timken representative.

Timken bearings are supplied with NORMAL RIC, unless otherwise specified. The desired RIC code must be added to the bearing number, FOLLOWING ALL OTHER SUFFIXES.

Min./max. values for each RIC are shown in the two adjacent columns directly beneath the selected RIC. Each single column represents a boundary between adjacent RICs. For example, the minimum values shown for C5 are also the maximum values for C4; minimum values for C4 are also the maximum values for C3; etc.

SPHERICAL ROLLER BEARING ENDPLAY

In certain applications such as vane pumps, rubber mill rotor shafts or where it is necessary to take up axial expansion within the bearing, knowledge of the bearing endplay relationship to mounted radial internal clearance may be required. The following table showing the ratio of approximate endplay to radial internal clearance in spherical roller bearings can be used to calculate approximate endplay in the bearing.

Example: 22320CJW33C3 bearing has a radial internal clearance after installation of .002. The total endplay would be approximately .0086 in. (± .0043 from center)

(1) For bearings with normal initial clearance.

: For bearings with normal initial clearance.

Min./Max. values for each RIC are shown in the two adjacent columns directly beneath the selected RIC. Each single column represents a boundary between adjacent RICs. For example, the minimum values shown for C5 are also the maximum values for C4; minimum values for C4 are also the maximum values for C3, etc.

* Special clearances can be provided (C6, C7, etc.)

A

MOUNTING DESIGNS - *continued*

CYLINDRICAL ROLLER BEARINGS

Cylindrical roller bearings are available with Radial Internal Clearance designations per either of the following tables: "Timken 'R' Clearance" or "ISO/ABMA 'C' Clearance." Non-standard values are also available by special request. Standard radial internal clearance values are listed in the following tables based on bore size. The clearance required for a given application depends on the desired operating precision, rotational speed of the bearing, and the fitting practice used. Most applications use a normal or C0 clearance. Typically, larger clearance reduces the operating zone of the bearing, increases the maximum roller load and reduces the bearing's expected life.

RADIAL CYLINDRICAL ROLLER BEARINGS

Min./Max. values for each RIC are shown in the two adjacent columns directly beneath the selected RIC. Each single column represents a boundary between adjacent RICs. For example, the minimum values shown for R5 are also the maximum values for R4; minimum values for R4 are also the maximum values for R3, etc. The desired RIC code (R1, R2, etc.) must be added to the bearing number, FOLLOWING ALL OTHER SUFFIXES.

RADIAL INTERNAL CLEARANCE LIMITS

All data on this chart are in millimeters/inches.

MOUNTING DESIGNS - *continued*

NEEDLE ROLLER BEARINGS

INSPECTION OF DRAWN CUP NEEDLE ROLLER BEARINGS

Although the bearing cup is accurately drawn from strip steel because of its fairly thin section, it may go out of round during heat treatment. When the bearing is pressed into a true round housing or ring gage, of correct size and wall thickness, it becomes round and is sized properly. **For this reason, it is incorrect to inspect an unmounted drawn cup bearing by measuring the outside diameter.** The correct method for inspecting the bearing size is to:

1. Press the bearing into a ring gage of proper size.
2. Plug the bearing bore with the appropriate "go" and "no go" gages or measure it with a tapered arbor (lathe mandrel).

Table 15 lists the "go" gage size for metric bearings which is the minimum needle roller complement bore diameter. The "no go" gage size is larger than the maximum needle roller complement bore diameter by 0.002 mm.

TABLE 15

50	57.967	50.025	50.050
60	67.967	60.030	60.060

* The ring gage sizes are in accordance with ISO N6 lower limit.

Inspection procedures

Table 15-B provides the correct ring and plug gage diameters for inspecting inch drawn cup needle roller bearings. When the letter H appears in the columns headed "Bearing Bore Designation" and "Nominal Shaft Diameter", the gage sizes listed are for the larger cross section bearings which include H in their bearing designation prefix.

Example

Find the ring gage and plug gage dimensions for a BH-68 bearing. The nominal bore diameter (F_W) for this bearing, as shown in the table of dimensions is .3750 inch. Since the letter H appears in the bearing designation, the following information will be found opposite H6 .3750 in Table 15-B.

	INCH
ring gage	.6255
diameter under needle rollers, min.	.3765
diameter under needle rollers, max.	.3774

The "go" plug gage is the same size as the minimum needle roller complement bore diameter and the "no go" plug gage size is .00001 inch larger than the maximum bore diameter. Therefore the correct ring and plug gage dimensions are:

	INCH
ring gage	.6255
plug gage, "go"	.3765
plug gage, "no go"	.3775

These same gage dimensions also apply to JH-68.

88	5 1/2	5.5000	5.9990	5.5010	5.5029

Bearing bore should be checked with "go" and "no go" plug gages. The "go" gage size is the minimum needle roller complement bore diameter. The "no go" gage size is larger than the maximum needle roller complement bore diameter by 0.0001 inch.

Inspection dimensions for the extra-precision bearings are given in the table below. Note that these bearings must be inspected while mounted in the specified ring gage. Bearing bores are checked with "go" and "no go" plug gages. The "go" gage size is the minimum diameter inside the needle rollers. The "no go" gage size is 0.0001 in. larger than the maximum diameter inside the needle rollers.

Procedures for selecting ring and plug gage dimensions are the same as for those involving precision needle bearings, except that the ring gage diameters and diameters inside the needle rollers must be drawn from the table on this page.

	Nominal shaft diameter inch	Ring gage	Diameter inside needle rollers ($F_{ws\ min}$) Min.	Max.

A

NEEDLE ROLLER CAGE ASSEMBLIES

Metric series needle roller and cage radial assemblies are supplied with needle roller complements subdivided into groups (gages) shown in Table 16. The groups are at Timken's option if nothing to the contrary is agreed upon at the time of ordering. This is in accordance with Grade G2 specified in ISO 3096 standard. The group limits of the needle rollers are indicated on the package. Labels of identifying colors show the group limits of the needle rollers. The needle roller and cage assemblies of one shipment usually contain needle rollers with group limits of between 0 to -2, and -5 to -7 µm (colors red, blue and white). Information on needle roller and cage assemblies with needle rollers of different group limits will be supplied on request.

TABLE 16

NEEDLE ROLLER GROUP LIMITS (GRADE G2)			
Group Tolerance µm		Marking	Identifying color of label or on package
0	-2	P0M2	
-1	-3	M1M3	red
-2	-4	M2M4	
-3	-5	M3M5	blue
-4	-6	M4M6	
-5	-7	M5M7	white (gray)
-6	-8	M6M8	
-7	-9	M7M9	green
-8	-10	M8M10	
-9	-11	M9M11	yellow

In the marking of the gages, P identifies zero (0) or plus (+), M identifies minus (-).

The nominal inch assemblies, WJ and WJC, contain needle rollers manufactured to only one diameter grade. Within any one assembly, the needle rollers have a total diameter tolerance of .0001 inch.

The limit to precision of the radial clearance of mounted needle roller and cage assemblies is the capability of the user to hold close tolerances on the inner and outer raceways.

The tolerance of the overall width of these assemblies is given on the tabular pages of this section.

It may be impractical to finish the shaft to meet desired raceway design requirements. In this case, standard needle roller bearings with inner rings (forming complete bearings) will have to be used. Such bearings meet the quality requirements in accordance with ISO standards.

- For inner and outer ring tolerances the metric series bearings follow the normal tolerance class in ISO Standard 492 covering radial bearings. Bearings to more precise tolerance classes P6 and P5 may be obtained upon request.
- The metric series bearings may be obtained with radial internal clearance in accordance with ISO Standard 5753 also specified for cylindrical roller bearings. Mostly, they follow the normal (C0) radial clearance group although bearings to clearance groups C2, C3, and C4 may be made available on request.
- Inner ring and outer ring chamfer dimensions meet the requirements of ISO Standard 582.

Whenever the shaft can be used as the inner raceway, needle roller bearings without inner rings provide advantages of economy and close control of radial internal clearance in operation. Tolerance class F6 is the normal specification for the metric series needle roller complement bore diameter of an unmounted bearing as shown in the following table. In the case of needle roller bearings of series RNAO, without flanges and without inner rings, the outer rings and needle roller and cage assemblies are not interchangeable.

METRIC SERIES NEEDLE ROLLER COMPLEMENT BORE DIAMETER FOR BEARINGS WITHOUT INNER RINGS

NEEDLE ROLLER BEARINGS

BEARINGS WITHOUT INNER RINGS

When the shaft is used as the inner raceway for needle roller bearings it must have a hardness between 58 and 64 HRC and a wave-free finish in order to realize the full load-carrying capability of the bearing.

1. **Metallurgy** – either case hardening or through hardening grades of good bearing quality steel are satisfactory for raceways. Steels which are modified for free machining, such as those high in sulfur content and particularly those containing lead, are seldom satisfactory for raceways.

   To realize full bearing capacity, the raceway area must be at least surface hard with a reasonable core strength. It is preferred that the case depth be not less than 0.42 mm (0.015 inches). The preferred surface hardness is equivalent to 58 HRC. If the raceway is of lesser hardness, see the modification factors shown on pages A39 and A34.

   The minimum effective case depth of hardened and ground raceways, for use with all types of needle roller bearings, depends on the applied load, the diameter of the rolling elements and the core strength of the steel used. To calculate the approximate case depth the following formula may be used:

   Min case depth = (0.07 to 0.12) • D_w

   D_w is the diameter of the rolling element.

   The high value should apply to a low core strength material and/or heavy loads.

   Note – The effective case is defined as the distance from the surface, after final grind, to the 50 HRC hardness level.

2. **Strength** – the shaft must be of sufficient size to keep the operating deflections within the limits outlined.

3. **Tolerance** – the suggested shaft diameter tolerances for each type of needle roller bearing are indicated in the appropriate section of this catalog.

4. **Variation of mean shaft diameter** – within the length of the bearing raceway should not exceed 0.008 mm (0.0003 inches), or one-half the diameter tolerance, whichever is smaller.

5. **Deviation from circular form** – the radial deviation from true circular form of the raceway should not exceed 0.0025 mm (0.0001 inches) for diameters up to and including 25 mm (1.0 inches). For raceways greater than 25 mm (1.0 inches) the allowable radial deviation should not exceed 0.0025 mm (0.0001 inch) multiplied by a factor of the raceway diameter divided by 25 for mm (1.0 for inches).

6. **High frequency lobing** – the lobing which occurs 10 or more times around the circumference of a shaft and exceeds 0.4 µm (15 microinches) peak-to-valley is defined as chatter. Chatter usually causes undesirable noise and reduces fatigue life.

7. **Surface finish** – In addition to a wave-free finish the raceway surface roughness of R_a ≤ 0.2 µm (8.0 microinches) must be maintained for the bearing to utilize its full load rating. The raceway area must also be free of nicks, burrs, scratches and dents. Oil holes are permissible in the raceway area but care must be taken to blend the edges gently into the raceway, and if possible, the hole should be located in the unloaded zone of the raceway.

   Care must also be taken to prevent grind reliefs, fillets, etc., from extending into the raceway area. If the rollers overhang a grind relief or step on the shaft, there will be high stress concentration with resultant early damage.

8. **End chamfer** – for the most effective assembly of the shaft into a bearing, the end of the shaft should have a large chamfer or rounding. This should help in preventing damage to the roller complement, scratching of the raceway surface and nicking of the shaft end.

9. **Sealing surface** – in some instances bearings have integral or immediately adjacent seals that operate on the surface ground for the bearing raceway. Here, particular attention should be paid to the pattern of the shaft finish. In no instance should there be a "lead" or spiral effect, as often occurs with through feed centerless grinding. Such a "lead" may pump lubricant past the seal.

BEARINGS WITH INNER RINGS

When it is undesirable or impractical to prepare the shaft to be used as a raceway, inner rings are available as listed in the tabular pages. If the shaft is not used directly as a raceway, the following design specifications must be met:

1. **Strength** – the shaft must be of sufficient size to keep the operating deflections within the limits outlined.

2. **Tolerance** – the suggested shaft diameter tolerances for each type of needle roller bearing are indicated in the appropriate section of the catalog.

3. **Variation of mean shaft raceway diameter and deviation from circular form of the raceway** – should not exceed one-half the shaft diameter tolerance.

4. **Surface finish** – the surface finish should not exceed R_a 1.6 µm (63 microinches).

5. **Locating shoulders or steps** – locating shoulders or steps in the shaft must be held to close concentricity with the bearing seat to prevent imbalance and resultant vibrations.

A

MOUNTING DESIGNS - *continued*

NEEDLE ROLLER BEARINGS
BEARINGS WITH OUTER RINGS

For bearings with outer rings, the function of the housing is to locate and support the outer ring. The following specifications must be met:

1. **Strength** – housings should be designed so that the radial loads, which will be placed on the bearings, will cause a minimum of deflection or distortion of the housing.

2. **Variation of mean housing diameter** – within the length of the outer ring should not exceed 0.013 mm (0.0005 inches).

3. **Deviation from circular form** – the housing bore should be round within one-half the housing bore tolerance.

4. **Parallelism** – when possible, line bore housings which are common to one shaft to obtain parallelism of the housing bores and the shaft axis.

5. **Surface finish** – The surface finish should not exceed R_a 1.6 µm (63 microinches).

6. **End chamfer** – to permit easy introduction of the bearing into the housing, the end of the housing should have a generous chamfer.

Needle roller bearings can be installed into housings with a transition fit or a clearance fit. The outer ring should be a transition fit in the housing when it rotates relative to the load. The outer ring may be a clearance fit in the housing when it is stationary relative to the load in either case, locate the bearings by shoulders, or other locating devices, to prevent axial movement.

Since the needle roller bearing does not require an interference fit in the housing to round and size it properly, a split housing may be used if desired. Dowels should be used to maintain proper register of the housing sections.

Drawn cup bearings have a thin case-hardened outer ring which is out-of-round from the hardening operation. For proper mounting it must **always** be pressed into the housing. Split housings will not round and size a drawn cup bearing. When split housings must be used, the bearing should first be mounted in a cylindrical sleeve.

The housing should be of sufficient tensile strength and section to round and size the bearing. It must be designed for minimum distortion under load. Steel or cast iron housings are preferred. Housing bores in low tensile strength materials such as aluminum, magnesium, phenolics, etc., should be reduced to provide more interference fit. Thin section cast iron and steel housings may also require reduced bores. Consult your Timken representative for suggestions when working with these lower strength housings.

The housing should be through-bored if possible. When shouldered housing bores are unavoidable, the bearing should be located far enough from the shoulder to avoid the danger of crushing the end of the drawn cup during installation.

When the drawn cup bearing is mounted close to the housing face, care should be taken to mount the bearing at least 0.25 mm (0.010 inches) within the housing face to protect the bearing lip.

BEARINGS WITHOUT OUTER RINGS

In many cases, such as with gear bores, it is desirable to have the housing bore serve as the outer raceway for radial needle roller and cage assemblies or loose needle roller complements. In those instances, as for shafts used as a raceway, the housing bore must have a hardness between 58 and 64 HRC and a roughness $R_a \leq 0.2$ µm (8.0 microinches), so that the full load carrying capacity of the bearing is realized.

1. **Strength** – the housing must be of sufficient cross section to maintain proper roundness and running clearance under maximum load.

2. **Metallurgical** – material selection, hardness and case depth should be consistent with the requirements for inner raceways given in the shaft design.

3. **Variation of mean housing raceway diameter and deviation from circular form of the raceway** – the raceway out-of-roundness and taper should not exceed 0.008 mm (0.0003 inches) or one-half the bore tolerance, whichever is smaller. In addition, the bore diameter must never be smaller at both ends than in the center [sway-back].

4. **Surface finish** – In addition to a wave-free finish, the raceway surface roughness of $Ra \leq 0.2$ µm (8.0 microinches) must be maintained for the bearing to utilize its full load rating. The raceway area must also be free of nicks, burrs, scratches and dents.

5. **Grind reliefs** – care must be exercised to ensure that grind reliefs, fillets, etc. do not extend to the raceway. Oil holes in the raceway area are permissible, but the edges must be blended smoothly with the raceway, and if possible, the hole should be located in the unloaded zone of the raceway.

MOUNTING DESIGNS - *continued*

ADDITIONAL DETAILS ABOUT DRAWN CUP NEEDLE BEARINGS

Drawn cup bearings are manufactured to a degree of precision that will satisfy the radial clearance requirements of most applications. The total radial clearance for an installed drawn cup bearing results from the build up of manufacturing tolerances of the housing bore, the inner raceway diameter and the bearing, as well as the minimum radial clearance required for the application.

For metric series drawn cup bearings requiring close control of radial internal clearance the suggested housing bore tolerance is N6 and h5 tolerance for the inner raceway diameter. When such exacting close control of radial internal clearance is not required, the user may select N7 housing bore and h6 inner raceway diameter tolerances.

For metric series drawn cup bearings used in housings made from materials of low rigidity or steel housings of small section the suggested housing bore tolerance is R6 (R7). To maintain normal radial internal clearance the inner raceway diameter tolerance should be h5 (h6).

For metric series drawn cup bearing applications where the outer ring rotates with respect to the load, it is suggested that both the housing bore and the inner raceway diameter be reduced using R6 (R7) and f5 (f6) tolerance practice respectively.

Metric series drawn cup bearing applications involving oscillating motion may require reduced radial internal clearances. This reduction may be accomplished by increasing the inner raceway diameter using j6 tolerance.

When it becomes impractical to meet the shaft raceway design requirements (hardness, case depth, surface finish etc.) outlined in this section, standard inner rings may be used with metric series drawn cup bearings. It is suggested that when metric series inner rings are used with metric series drawn cup bearings, they should be mounted with a loose transition fit on the shaft using g6 (g5) shaft diameter tolerance. The inner ring should be endclamped against a shoulder. If a tight transition fit must be used, [shaft diameter tolerance h6 (h5)], to keep the inner ring from rotating relative to the shaft, the inner ring outside diameter, as mounted, must not exceed the raceway diameter required by the drawn cup bearing for the particular application. In case the outside diameter of the inner ring, when mounted on the shaft, exceeds the required raceway diameter for the matching drawn cup bearing, it should be ground to proper diameter while mounted on the shaft.

Inch drawn cup needle roller bearings utilize the standard tolerance scheme outlined in the following figure.

Fig. A-14

MOUNTING DESIGNS - *continued*

For housing materials of low rigidity or steel housings of small section, it is suggested that for initial trial the housing bore diameters given in the tabular pages be reduced by the amounts shown in Table 21. To maintain normal radial internal clearance, the inner raceway diameter tolerance given in the tabular pages should be used.

TABLE 21

LOW RIGIDITY HOUSING BORE		
Nom. Housing Bore Inch		Subtract Inch
over	incl.	
0	.38	.0004
.38	1.00	.0006
1.00	2.00	.0010
2.00	3.00	.0012
3.00	6.00	.0014

For applications where the outer ring rotates with respect to the load, it is suggested that both the housing bore and inner raceway diameter be reduced. Bearings of nominal inch dimensions should have the housing bore and inner raceway diameters reduced by .0005".

Applications involving oscillating motion often require reduced radial clearances. This reduction is accomplished by increasing the shaft raceway diameters as shown in Table 22.

TABLE 22

NOMINAL INCH BEARING OSCILLATING SHAFT SIZE	
Shaft Size	Add
inch	inch
.094 to .188	.0003
.25 to 1.875	.0005
2 to 5.5	.0006

Where it becomes impractical to meet the shaft raceway design requirements (hardness, case depth, surface finish, etc.) standard inner rings for inch drawn cup bearings are available.

Inner rings for inch drawn cup bearings are designed to be a loose transition fit on the shaft and should be clamped against a shoulder. If a tight transition fit must be used to keep the inner ring from rotating relative to the shaft, the inner ring O.D., as mounted, must not exceed the raceway diameters required by the drawn cup bearing for the particular application. See the previous discussion on internal clearances and fits for further details on inner raceway diameter choice.

MOUNTING DESIGNS - *continued*
INSTALLATION OF DRAWN CUP BEARINGS
General installation requirements

- A drawn cup bearing must be pressed into its housing.

- An installation tool, similar to the ones shown, must be used in conjunction with a standard press.

- The bearing must not be hammered into its housing, even in conjunction with the proper assembly mandrel.

- The bearing must not be pressed tightly against a shoulder in the housing.

- If it is necessary to use a shouldered housing, the depth of the housing bore must be sufficient to ensure the housing shoulder fillet, as well as the shoulder face, clears the bearing.

- The installation tool must be co-axial with the housing bore.

INSTALLATION OF OPEN END BEARINGS

It is advisable to utilize a positive stop on the press tool to locate the bearing properly in the housing. The assembly tool should have a leader or a pilot, as shown, to aid in starting the bearing true in the housing. The ball detent shown on the drawing is used to assist in aligning the rollers of a full complement bearing during installation and to hold the bearing on the installation tool. A caged type drawn cup bearing does not require a ball detent to align its rollers. The ball detent may still be used to hold the bearing on the installation tool or an "O" ring may be used. The bearing should be installed with the stamped end (the end with identification markings) against the angled shoulder of the pressing tool.

INCH BEARINGS

A – $\frac{1}{64}$ in. less than housing bore
B – .003 in. less than shaft diameter
C – distance bearing will be inset into housing, minimum of .008 in.
D – pilot length should be length of bearing less $\frac{1}{32}$ in.
E – approximately $\frac{1}{2}$ D

METRIC BEARINGS

A – 0.4 mm less than housing bore
B – 0.08 mm less than shaft diameter
C – distance bearing will be inset into housing, minimum of 0.2 mm
D – pilot length should be length of bearing less 0.8 mm
E – approximately $\frac{1}{2}$ D

Stamped end of bearing

Generous chamfer or rounding for easy bearing installation

### DRAWN CUP NEEDLE ROLLER BEARINGS – INCH
Installation of closed end bearings

The installation tool combines all the features of the tool used to install open end bearings, but the pilot is spring-loaded and is part of the press bed.

The angled shoulder of the pressing tool should bear against the closed end with the bearing held on the pilot to aid in starting the bearing true in the housing.

A – 1/64 in. less than housing bore
B – .003 in. less than shaft diameter
C – distance bearing will be inset into housing, minimum of .008 in.
Extraction of drawn cup bearings

The need to extract a drawn cup bearing does not arise often. Standard extractor tools may be purchased from a reputable manufacturer. Customers may produce the special extraction tools at their own facilities. After extraction, the drawn cup bearing should not be reused.
Extraction from a straight housing

When it is necessary to extract a drawn cup bearing from a straight housing, a similar tool to the installation tool, but without the stop, may be used. To avoid damage to the bearing, pressure should be applied against the stamped end of the bearing, just as it is done at installation.
MOUNTING DESIGNS - *continued*
DRAWN CUP NEEDLE ROLLER BEARINGS
Extraction from a shouldered or dead-end housing (with space between the bearing and the housing shoulder)

Bearings may be extracted from shouldered or dead-end housings with a common bearing puller tool as shown. This type of tool is slotted in two places at right angles to form four prongs. The four puller prongs are pressed together and inserted into the space between the end of the bearing and the shoulder. The prongs are forced outward by inserting the expansion rod, and then the bearing is extracted. Do not reuse the bearing after extraction.

Two Slots 90° Apart

Wrench

Expansion Rod

Extraction from a shouldered housing (with bearing pressed up close to the shoulder)

The tool to be used, as shown, is of a similar type described for a shouldered or dead-end housing, but the rollers must first be removed from the bearing.

The four segment puller jaws are collapsed and slipped into the empty cup. The jaws are then forced outward into the cup bore by means of the tapered expansion rod. The jaws should bear on the lip as near as possible to the cup bore. The cup is then pressed out from the top.

DRAWN CUP ROLLER CLUTCHES
Housing design

Drawn cup clutches and clutch and bearing assemblies are mounted with a simple press fit in their housings. Through bored and chamfered housings are preferred. Provisions for axial location, such as shoulders or snap rings, are not required. The case hardened cups must be properly supported. Steel housings are preferred and must be used for applications involving high torque loads to prevent radial expansion of the clutch cups. The suggested minimum housing outside diameters in the tables of dimensions are for steel.

The housing bore should be round within one-half of the diameter tolerance. The taper within the length of the outer ring should not exceed 0.013 mm or 0.0005 inch.

The surface finish of the housing bore should not exceed 63 microinches, a.a. (arithmetic average) or 1.6 µm (on the Ra scale).

Low strength housings (non-steel, sintered metals and some plastics) may be entirely satisfactory in lightly loaded applications. When using non-steel housings, thoroughly test designs.

Adhesive compounds can be used to prevent creeping rotation of the clutch in plastic housings with low friction properties. Adhesives will not provide proper support in oversized metallic housings. When using adhesives, care must be taken to keep the adhesive out of the clutches and bearings.

• •

Shaft design

The clutch or bearing assembly operates directly on the shaft whose specifications of dimensions, hardness and surface finish are well within standard manufacturing limits.

Either case hardening or through hardening grades of good bearing quality steel are satisfactory for raceways. Steels which are modified for free machining, such as those high in sulfur content and particularly those containing lead, are seldom satisfactory for raceways.

For long fatigue life, the shaft raceway, must have a hardness equivalent to 58 HRC (ref, ASTM E-18), and ground to the suggested diameter shown in the tables of dimensions. It may be through hardened, or it may be case hardened, with an effective case depth of 0. mm (0.015 inch) (Effective case depth is defined as the distance from the surface inward to the equivalent of 50 HRC hardness level after grinding.)

Taper within the length of the raceway should not exceed 0.008 mm (0.0003 inch), or one-half the diameter tolerance, whichever is smaller. The radial deviation from true circular form of the raceway should not exceed 0.0025 mm (.0001 inch) for diameters up to and including 25.4 mm (1 inch). For raceways greater than 25 mm or 1.0 inch the allowable radial deviation may be greater than 0.0025 mm (.0001 inch) by a factor of raceway diameter (in inches) divided by 1.0 or a factor of raceway diameter (in mm) divided by 25.4. Surface finish on the raceway should not exceed 16 microinches a.a. (arithmetic average) or 0.4 µm (on the Ra scale). Deviations will reduce the load capacity and fatigue life of the shaft.

MOUNTING DESIGNS - *continued*

Installation

Simplicity of installation promotes additional cost savings. The drawn cup roller clutch or the clutch and bearing assembly must be pressed into its housing. The unit is pressed into the bore of a gear hub or pulley hub or housing of the proper size and no shoulders, splines, keys, screws or snap rings are required.

Installation procedures are summarized in the following sketches:
Use an arbor press or hydraulic ram press which will exert steady pressure. Never use a hammer or other tool requiring pounding to drive the clutch into its housing.
Make sure that the housing bore is chamfered to permit easy introduction of the clutch and bearing or the clutch unit. Press unit slightly beyond the chamfer in the housing bore to assure full seating. Through bored housings are always preferred. If the housing has a shoulder, never seat the clutch against the shoulder.

IMPORTANT: The mounted clutch or clutch and bearing assembly engages when the housing is rotated relative to the shaft in the direction of the arrow and LOCK marking (← LOCK) stamped on the cup. Make sure that the unit is oriented properly before pressing it into its housing.
Use an installation tool as shown in the diagram above. If clutch is straddled by needle roller bearings, press units into position in proper sequence and preferably leave a small clearance between units.
When assembling the shaft, it should be rotated during insertion. The end of the shaft should have a large chamfer or rounding.

A

MOUNTING DESIGNS - *continued*

RADIAL NEEDLE ROLLER AND CAGE ASSEMBLIES – METRIC

Radial needle roller and cage radial assemblies use the housing bore as the outer raceway and the shaft as the inner raceway. In order to realize full bearing load rating, the housing bore and the shaft raceways must have the correct geometric and metallurgical characteristics. The housing should be of sufficient cross section to maintain adequate roundness and running clearance under load. The only limit to precision of the radial clearance of a mounted assembly is the capability of the user to hold close tolerances on the inner and outer raceways. The suggested shaft tolerances listed in Table 23 are based on housing bore tolerance G6 and apply to metric series needle roller and cage radial assemblies with needle rollers of group limits between P0M2 and M5M7. Inch cage and roller assemblies list shaft tolerances in the bearing data tables based on h5 tolerances and housings to G6 tolerances.

TABLE 23

SUGGESTED SHAFT TOLERANCES FOR METRIC BEARINGS USING HOUSING BORES MACHINED TO G6 AS OUTER RACEWAYS		
Nominal shaft diameter in mm	≤ 80	> 80
Radial clearance	Shaft tolerance	
Smaller than normal	j5	h5
Normal	h5	g5
Larger than normal	g6	f6

Needle roller and cage radial assembly must be axially guided by shoulders or other suitable means. The end guiding surfaces should be hardened to minimize wear and must provide sufficient axial clearance to prevent end locking of the assembly. Metric length tolerance H11 is suggested. Inch bearings are designed for minimum 0.008 inch axial clearance.

If end guidance is provided by a housing shoulder at one end and by a shaft shoulder at the other end the shaft must be axially positioned to prevent end locking of needle roller and cage assembly. The housing and shaft shoulder heights should be 70 to 90 percent of the needle roller diameter to provide proper axial guidance.

Guidance in the housing   Guidance on the shaft
Needle roller and cage radial assemblies which are mounted side by side must have needle rollers of the same group limits to ensure uniform load distribution.

Connecting rod guidance arrangements

End guidance of a connecting rod can be provided either at the crank pin or at the wrist pin end. Connecting rod guidance is achieved at the crank pin end using a small clearance between the crank webs. Guidance at the wrist pin end is controlled by a small clearance between the piston bosses.

Crank pin end guidance

With crank pin end guidance, care must be taken to ensure that an adequate amount of lubricant is supplied to the crank pin bearing and the surfaces which guide the connecting rod. For this purpose, grooves in the connecting rod end faces or slots in the connecting rod bore aligned with the incoming lubrication path should be provided. Occasionally, brass or hardened steel washers may be used for end guidance of the connecting rod.

At the wrist pin end, the needle roller and cage radial assembly is located axially between the piston bosses. It may be both economical and effective to machine the connecting rod at the wrist pin end and at the crank pin end to the same width. It is suggested that at the wrist pin end, the needle roller length does not overhang the connecting rod width. Otherwise the load rating of the needle roller and cage assembly will be reduced.

Wrist pin end guidance

Wrist pin end will get the most effective axial guidance between the piston bosses. Grooves in the bottom of the piston bosses and a chamfer of small angle on each side of the upper portion of the connecting rod small end, can improve the oil flow to the needle roller and cage radial assembly and its guiding surfaces.

The length of the needle roller and cage radial assembly and the connecting rod width at the crank pin end should be identical to ensure best possible radial piloting of cage in the bore of the connecting rod. The crank webs are recessed to allow proper axial alignment of the connecting rod. As a rule it is not necessary to have additional supply of lubricant. Only in engines with sparse lubrication should consideration be given to provide lubricating slots in the connecting rod bores as with crank pin end guidance.

MOUNTING DESIGNS - *continued*
NEEDLE ROLLER BEARINGS
Heavy-duty needle roller bearings

It is suggested that needle roller bearings are mounted in their housings with a clearance fit if the load is stationary relative to the housing or with a tight transition fit if the load rotates relative to the housing. Table 24 lists the suggested tolerances for the housing bore and the shaft raceway for metric series bearings without inner rings. Table 25 lists the suggested shaft tolerances for the above two mounting conditions when the metric series bearings are used with inner rings. The suggested housing bore tolerances for metric series bearings with inner rings are the same as the housing bore tolerance listed in Table 24 for metric series bearings without inner rings.

The tables of dimensions for inch bearings list the suggested ISO H7 tolerances for the housing bore and the suggested ISO h6 tolerances for the shaft raceway when the outer ring is to be mounted with a clearance fit. They also list the suggested ISO N7 tolerances for the housing bore and the suggested ISO f6 tolerances for the shaft raceway when the outer ring is to be mounted with a tight transition fit.

Other mounting dimensions may be required for special operating conditions such as:
1. Extremely heavy radial loads
2. Shock loads
3. Temperature gradient across bearing
4. Housing material with heat expansion coefficient different than that of the bearing

If these conditions are expected, please consult your Timken representative.

TABLE 24

MOUNTING TOLERANCES FOR METRIC SERIES BEARINGS WITHOUT INNER RING						
Rotation conditions	Nominal housing bore diameter D	ISO tolerance zone for housing		Nominal shaft diameter F	ISO tolerance zone for shaft	
	mm	caged	full	mm	caged	full

load stationary relative to housing	> ≤ 40 40 100 100 140 140	k6 m6 m6 n6

NOTE: Care should be taken that the selected bearing internal clearance is appropriate for the operating conditions.

TABLE 26

FILLETS, UNDERCUTS, AND SHOULDER HEIGHTS FOR METRIC SERIES BEARINGS					
r_s Min. mm	r_{as} Max.	t	r_{a2s} Min.	b	h Min.
0.15	0.15				0.6
0.3	0.3				1
0.6	0.6				2
1	1	0.2	1.3	2	2.5
1.1	1	0.3	2	3	3.25
1.5	1.5	0.4	2	3.2	4
2	2	0.5	2.5	4	5
2.1	2.1	0.5	3	4.7	5.5
3	2.5	0.5	3.5	5	3 6

Regardless of the fit of the bearing outer ring in the housing, the outer ring should be axially located by housing shoulders or other positive means. The bearing rings should closely fit against the shaft and housing shoulders and must not contact the fillet radius. In fact, the maximum shaft or housing fillet $r_{as\ max}$ should be no greater than the minimum bearing chamfer $r_{s\ min}$ as shown in Table 26.

In order to permit mounting and dismounting of the shaft, the maximum diameter D_1 in Table 27 must not be exceeded. F_w is shown in the bearing tables.

For inch bearings, the unmarked end of the outer ring should be assembled against the housing shoulder to assure clearing the maximum housing fillet. Similarly, the unmarked end of the inner ring should be assembled against the shaft shoulder to assure clearing the maximum shaft fillet.

MOUNTING DESIGNS - *continued*

TABLE 27

SHOULDER DIAMETER D$_1$ MAX FOR METRIC SERIES BEARINGS						
Dimensions in mm						
Needle roller complement bore diameter F$_W$	>		20	55	100	250
	≤	20	55	100	250	
Diameter	D$_{1max}$	F$_W$ -0.3	F$_W$ -0.5	F$_W$ -0.7	F$_W$ -1	F$_W$ -1.5

Needle roller bearings without flanges of series RNAO and NAO must have the needle roller and cage radial assembly properly end guided by shoulders or other suitable means such as the spring steel washers (SNSH). These end guiding surfaces should be hardened and precision turned or ground to minimize wear and should properly fit against the outer rings and the inner rings to provide the desired end clearance for the needle roller and cage radial assembly.

NEEDLE ROLLER AND CAGE THRUST ASSEMBLIES

On NTA inch type needle roller and cage thrust assemblies the cage bore has a larger contact area and a closer tolerance than the outside diameter. Therefore, bore piloting is preferred for these assemblies. To reduce wear, it is suggested that the piloting surface for the cage be hardened to an equivalent of at least 55 HRC. Where design requirements prevent bore piloting, the NTA needle roller and cage thrust assemblies may be piloted on the outside diameters. It should be noted that the "diameter to clear washer O.D. " given in the tabular data is not suitable for outside diameter piloting. For such cases, suitable O.D. piloting dimensions should be determined in consultation with your Timken representative.

On FNT and AXK Series needle roller and cage thrust assemblies, the cage bore has a closer tolerance than the outside diameter, therefore bore piloting is preferred for these assemblies. To reduce wear, it is suggested that the piloting surface for the cage be hardened to an equivalent of at least 55 HRC. Where design requirements prevent bore piloting, the FNT or AXK Series needle roller and cage thrust assemblies may be piloted on the outside diameters. For such cases, suitable O.D. piloting dimensions should be determined. Mounting tolerances are given in the table to the right.

Ideally, a thrust washer should be stationary with respect to, and piloted by, its supporting or backing member, whether or not this is an integral part of the shaft or housing. There should be no rubbing action between the thrust washer and any other machine member. The economics of design, however, often preclude these ideal conditions and thrust washers must be employed in another manner. In such cases, design details should be determined in consultation with your Timken representative.

The mounting tolerances for series AS, LS, WS and GS thrust washers for use with needle roller and cage thrust assemblies are given in the table to the right.

As for the FNT and AXK Series thrust assemblies, to reduce wear, the piloting surface for the thrust washers should also be hardened to an equivalent of at least 55 HRC.

Out of Square Surface

Dished or Coned Surface
Fig. A-16

MOUNTING TOLERANCES FOR SHAFTS AND HOUSINGS FOR METRIC SERIES COMPONENTS			
Bearing components	**shaft tolerance**	**housing tolerance (shaft piloting)**	**piloting member (housing piloting)**
Cylindrical roller & needle roller cage thrust assembly	h8	H10	shaft
Thin thrust washer AS	h10	H11	shaft
Heavy thrust washer LS	h10	H11	shaft
Shaft piloted thrust washer WS.811	h6 (j6)	clearance	shaft
Housing piloted thrust washer GS.811	Clearance	H7 (K7)	housing

In some applications, it is desirable to use the backup surfaces as raceways for the needle rollers of the needle roller and cage thrust assemblies. In such designs, these surfaces must be hardened to at least 58 HRC. If this hardness cannot be achieved and thrust washers cannot be used, the load ratings must be reduced, as explained in the Fatigue Life section.

Thrust raceway surfaces must be ground to a surface finish of 0.2 µm (0.8 µm) R$_a$. When this requirement cannot be met, thrust washers must be used.

The raceways against which the needle rollers operate or the surface against which the thrust washers bear must be square with the axis of the shaft. Equally important, the raceway or surface backing the thrust washer, must not be dished or coned. The permissible limits of out-of-squareness and dishing or coning are shown in Figures A-15 and A-16.

Metric raceway contact dimensions E$_a$ and E$_b$ are given in the tabular pages. For the thin series AS thrust washers, full backup between the dimensions E$_a$ and E$_b$ should be provided.

A

MOUNTING DESIGNS - *continued*

CONSTRUCTION
Basic designs

Cylindrical roller thrust bearings dimension series 811 and 812 comprise a cylindrical roller and cage thrust assembly (K), a shaft washer (WS) and a housing washer (GS). Providing the backup surfaces can be hardened and ground they can be used as raceways for the cylindrical rollers of the cylindrical roller and cage thrust assembly, resulting in a compact bearing arrangement.

Cage designs

Metric series cylindrical roller thrust bearings use molded cages of glass fiber reinforced nylon 6/6 (suffix TVP) or machined cages of light metal (suffix LPB). The cages are designed to be piloted on the shaft. The reinforced nylon cages can be used at temperatures up to 120° C continuously for extended periods. When lubricating these bearings with oil it should be ensured that the oil does not contain additives detrimental to the cage over extended life at operating temperatures higher than 100° C. Also, care should be exercised that oil change intervals are observed as old oil may reduce cage life at such temperatures.

BEARING THRUST WASHERS
Shaft washers and housing washers

Shaft washers of types WS.811 and WS.812 as well as housing washers of types GS.811 and GS.812 are components of the metric series cylindrical roller thrust bearings of series 811 and 812. They are made of bearing quality steel, with hardened and precision ground and lapped flat raceway surfaces. The tolerances of the thrust bearing bore and outside diameter shown in Table 7 and Table 8 (on page A47) apply to shaft and housing piloted metric series washers.

Heavy thrust washers (LS), thin thrust washers (AS)

These thrust washers, more frequently used with needle roller and cage thrust assemblies of metric series FNT or AXK, are also suitable for use with the cylindrical roller and cage thrust assemblies K.811. The heavy thrust washer of series LS are made of bearing quality steel, hardened and precision ground on the flat raceway surfaces. The bore and outside diameters of the heavy thrust washers are not ground. Therefore, when used with K.811 type assemblies they are only suggested where accurate centering is not required. The thin thrust washers of series AS may be used in applications where the loads are light. Both types of these washers are listed in the tabular part of the metric series needle roller and cage thrust assemblies section.

MOUNTING DESIGNS - *continued*

DIMENSIONAL ACCURACY

The tolerances for the metric series cylindrical roller thrust bearing bore and outside diameter shown in Tables 7 and 8 (on page A47) apply to shaft piloted washers of series WS.811 and WS.812 as well as housing piloted washers of series GS.811 and GS.812.

The tolerances for the bore and outside diameter of series AS thrust washers are shown in Table 13. The tolerances for the bore and outside diameter of series LS thrust washers are given in Table 14. Bore inspection procedures for thin thrust washers (AS) and heavy thrust washers (LS) are given on page A50.

MOUNTING TOLERANCES

Shaft and housing tolerances for mounting metric series cylindrical roller and cage thrust assemblies are given on page A96. If the cylindrical rollers of the cylindrical roller and cage thrust assemblies are to run directly on the adjacent support surfaces, these must be hardened to at least 58 HRC. Raceway contact dimensions E_a and E_b must be observed.

The backup surfaces for the shaft washers WS.811 and WS.812 as well as the housing washers GS.811 and GS.812 of cylindrical roller thrust bearings must be square with the axis of the shaft. Equally important, the raceway or the surface backing the thrust washer must not be dished or coned. The permissible limits of the squareness and dishing or coning are shown in Figures A-15 and A-16. When using the thin (AS) thrust washers the cylindrical rollers of the thrust cage assembly must be supported over their entire length.

Bearing thrust washers should make close contact with the shaft or housing shoulder and must not touch the fillet radius. Therefore, the maximum fillet radius $r_{as\ max}$ must be no greater than the minimum chamfer $r_{s\ min}$ of the shaft washer (WS) and the housing washer (GS).

THRUST BEARINGS

Tapered Roller thrust bearings are generally mounted with a fit range on the inside diameter of 127 μm (0.0050 in.) loose to 400 μm (0.0150 in.) loose. Sufficient clearance should be provided on the outside diameter to permit free centering of the bearing without interference.

When Type TTHD or TTHDFL thrust bearings are subjected to continuous rotation, the rotating race should be applied with a minimum interference fit of 25 μm (0.0010 in.). Sufficient clearance should be provided on the outside diameter of the stationary race to permit free centering of the bearing without interference.

A

MOUNTING DESIGNS - *continued*

TAPERED ROLLER BEARING MOUNTING PROCEDURE

Bearing performances can be adversely affected by improper mounting procedure or lack of care during the assembly phase.

Environment

Cleanliness during the bearing mounting operation is essential for a rolling bearing to operate for maximum service life. Bearings in their shipping containers or wrapping have been coated for rust protection. While this coating is not sufficient to properly lubricate the bearing, it is compatible with most lubricants and therefore does not have to be removed when mounting the bearing in the majority of applications. Burrs, foreign matter and damaged bearing seats cause misalignment. Care should be taken to avoid shearing or damaging bearing seats during assembly which may introduce misalignment or result in a change of bearing setting during operation.

Fitting

Adequate tools must be provided to properly fit the inner and outer races on shafts or in housings to avoid damage. Direct shock on the races must be avoided. Often, bearing races have to be heated or cooled to ease assembly. Do not heat standard bearings above 150° C (300° F) or freeze outer races below -55° C (-65° F). For precision bearings, do not heat above 65° C (150° F) or freeze below -30° C (-20° F). Note: For more information on this subject, please contact your Timken representative.

MOUNTING DESIGNS

The primary function of either the cone or cup backing shoulders is to positively establish the axial location and alignment of the bearing and its adjacent parts under all loading and operating conditions.

For a tapered roller bearing to operate for maximum service life, it is essential that a shoulder, square with the bearing axis and of sufficient diameter, is provided for each race. It must be of sufficient section and design to resist axial movement due to loading or distortion and must be wear-resistant at the interface with the bearing.

The conventional and most widely accepted method used to provide bearing backing is to machine a shoulder on a shaft or in the housing (Fig. A-17).

In some applications a spacer is used between a cone and shaft shoulder or a snap ring. As a further alternative, a split spacer can be used (Fig. A-18).

A spacer or snap ring can also be used for cup backing (Fig. A-19). If a snap ring is used for bearing backing it is suggested that an interference cup fit be used.

The cup used for bearing setting in a direct mounting (roller small ends pointing outwards) is usually set in position by a cup follower or by mounting in a carrier (Fig. A-20).

Fig. A-20
Bearing setting devices - direct mounting.

A

MOUNTING DESIGNS *- continued*

With an indirect mounting (roller small ends pointing inwards), bearing setting can be achieved by a wide variety of devices (Fig. A-21).

In applications requiring precision class bearings, a special precision nut can be used. This has a soft metal shoe that is clamped against the threads with a locking screw. Other solutions can use split nut and/or ground spacers where setting cannot be altered (Fig. A-22).

Snap rings

In instances where snap rings are used to locate bearing components, it is important that they are of sufficient section to provide positive location. Care must be taken during installation or removal of the snap ring to prevent damage to the bearing cage.

Removal

Suitable means must be provided on adjacent bearing parts for easy bearing removal. Knockout slots, puller grooves and axial holes can be designed into the backing surfaces to ease removal of the cup or cone for servicing (Fig. A-23). In specific cases, hydraulic devices can also be used.

Backing diameters

Backing diameters, fillet clearances and cage clearances are listed for each individual part number in the bearing tables. Backing shoulder diameters shown should be considered as minimum values for shafts and maximum values for housings.

NOTE: Do not use a backing diameter that provides less backing surface than suggested.

MOUNTING DESIGNS - *continued*

SEATING
Geometry

Two major causes of misalignment occur when the seats of cones and/or cups are machined out of square with the bearing axis or when the seats are parallel but out of alignment.

Surface finishes – standard bearings

For industrial applications, please refer to the following guidelines:

GROUND SHAFTS

All roller bearing shaft seats should be ground to a surface finish of 1.6 µm (65 µin) R_a maximum wherever possible. Ball bearing seats should be 0.8 µm (32 µin) for shafts under 2 inches and 1.6 µm (65 µin) for all other sizes.

TURNED SHAFTS

When shaft seats are turned, a tighter heavy-duty fit should be used. In this case the shaft diameter should be turned to a finish of 3.2 µm (125 µin) R_a maximum.

HOUSING BORES

Housing bores should be finished to 3.2 µm (125 µin) R_a maximum.

Surface finishes - precision bearings

Precision class bearings should be mounted on shafts and in housings that are finished to at least the same precision limits as the bearing bore or outside diameter.

Furthermore, high quality surface finishes together with close machining tolerances of bearing seats must also be provided. The following tabulations give some guidelines for all these criteria:

TAPERED ROLLER BEARINGS SURFACE FINISH – R_a (µm - µin) BEARING CLASS				
ALL SIZES	**C** **3**	**B** **0**	**A** **00**	**AA** **000**
Shaft	**0.8** 32	**0.6** 24	**0.4** 15	**0.2** 7
Housing	**1.6** 65	**0.8** 32	**0.6** 24	**0.4** 15

Correct fitting practice and precise bearing setting both affect bearing life, rigidity and, in the case of precision bearings, accuracy.

Improper fits will lead to problems such as poor machine performance including creeping of the cone on the spindle or the cup in the housing and lack of spindle stiffness.

The choice of fitting practices will mainly depend upon the following parameters:

- Precision class of the bearing.
- Rotating or stationary race.
- Type of layout (single/double-row bearings).
- Type and direction of load (continuous/alternate rotating).
- Particular running conditions like shocks, vibrations, overloading or high speed.
- Capability for machining the seats (grinding, turning or boring).
- Shaft and housing section and material.
- Mounting and setting conditions.
- Preadjusted tapered roller bearings must be mounted with the suggested fit.

SHAFT AND HOUSING FITS

Below is a graphical representation of shaft and housing fit selection for these bearings conforming to ANSI/ABMA Standard 7. The bars designated by g6, h6 etc., represent shaft/housing diameter and tolerance ranges to achieve various loose and interference fits required for various load and ring rotation conditions.

A
FITTING PRACTICES

TAPERED ROLLER BEARINGS

The design of a Timken tapered roller bearing allows the setting of bearing internal clearance during installation to optimize bearing operation.

General industrial application fitting practice standards for cones and cups are shown in the following tables. These tables apply to solid or heavy-sectioned steel shafts, heavy-sectioned ferrous housings and normal operating conditions. To use the tables, it is necessary to determine if the member is rotating or stationary, the magnitude, direction, and type of loading and the shaft finish.

Certain table fits may not be adequate for light shaft and housing sections, shafts other than steel, nonferrous housings, critical operation conditions such as high speed, unusual thermal or loading conditions or a combination thereof. Also assembly procedures and the means and ease of obtaining the bearing setting may require special fits. In these cases, experience should be used as a guideline or your Timken representative should be consulted for review and suggestions.

Rotating cones generally should be applied with an interference fit. In special cases loose fits may be considered if it has been determined by test or experience they will perform satisfactorily. The term "rotating cone" describes a condition in which the cone rotates relative to the load. This may occur with a rotating cone under a stationary load or a stationary cone with a rotating load. Loose fits will permit the cones to creep and wear the shaft and the backing shoulder. This will result in excessive bearing looseness and possible bearing and shaft damage.

Stationary cone fitting practice depends on the application. Under conditions of high speed, heavy loads or shock, interference fits using heavy-duty fitting practice should be used. With cones mounted on unground shafts subjected to moderate loads (no shock) and moderate speeds, a metal-to-metal or near zero average fit is used. In sheave and wheel applications using unground shafts, or in cases using ground shafts with moderate loads (no shock), a minimum fit near zero to a maximum looseness which varies with the cone bore size is suggested. In stationary cone applications requiring hardened and ground spindles, a slightly looser fit may be satisfactory. Special fits may also be necessary on installations such as multiple sheave crane blocks.

Rotating cup applications where the cup rotates relative to the load should always use an interference fit.

Stationary, nonadjustable and fixed single-row cup applications should be applied with a tight fit wherever practical. Generally, adjustable fits may be used where the bearing setup is obtained by sliding the cup axially in the housing bore. However, in certain heavy-duty, high-load applications, tight fits are necessary to prevent pounding and plastic deformation of the housing. Tightly fitted cups mounted in carriers can be used. Tight fits should always be used when the load rotates relative to the cup.

To permit through-boring when the outside diameters of single-row bearings mounted at each end of a shaft are equal and one is adjustable and the other fixed, it is suggested that the same adjustable fit be used at both ends. However, tight fits should be used if cups are backed against snap rings, to prevent excessive dishing of snap rings, groove wear and possible loss of ring retention. Only cups with a maximum housing fillet radius requirement of 1.3 mm (0.05 in.) or less should be considered for a snap ring backing.

Two-row stationary double cups are generally mounted with loose fits to permit assembly and disassembly. The loose fit also permits float when a floating bearing is mounted in conjunction with an axially fixed bearing on the other end of the shaft.

The fitting practice tables that follow have been prepared for both metric and inch dimensions.

For the inch system bearings, classes 4 and 2 (standard) and classes 3, 0, and 00 (precision) have been included.

The metric system bearings that have been included are: Classes K and N (metric system standard bearings) and classes C, B, and A (metric system precision bearings).

Precision class bearings should be mounted on shafts and in housings which are similarly finished to at least the same precision limits as the bearing bore and O.D. High quality surface finishes should also be provided.

Two-row and four-row bearings, which are provided with spacers and shipped as matched assemblies, have been preset to a specific bench endplay. The specific endplay setting is determined from a study of the bearing mounting and expected environment. It is dependent on the fitting practice and the required mounted bearing settings.

For rolling mill neck fitting practice, consult your Timken representative. For all other equipment associated with the rolling mill industry, the fitting practice suggestions in the tables that follow should be used.

In addition to all other axial tolerances and the overall bearing width tolerance, the width increase due to tight fits of the cone or cup, or both, must be considered when axial tolerance summation calculations are made. By knowing the fit range, the minimum and maximum bearing width increase can be determined to establish the initial design dimensions. For instance, all tolerances plus the bearing width increase range due to tight fits must be known in order to calculate the shim gap range that would occur on a cup adjusted, direct mounting design.

In a factory preset bearing or a SET-RIGHT™ mounting, where the bearing overall width is fixed and clamped, tight fits will cause cup expansion or cone contraction which will reduce the internal clearance (endplay) within the bearing.

Endplay Removed for Single Cone

$$= 0.5 \left(\frac{K}{0.39} \right) \left(\frac{d}{d_o} \right) \delta_S$$

The following equations under Normal Sections and Thin Wall Sections can be used to calculate endplay removed in a similar manner.

where:
- K = Tapered Roller Bearing Radial-to-Axial Dynamic Load Rating Factor
- d = Bearing Bore Diameter
- d_o = Mean Inner Race Diameter
- D_o = Mean Outer Race Diameter
- d_S = Shaft Inside Diameter
- D = Bearing Outside Diameter
- D_H = Housing Outside Diameter
- δ_S = Interference Fit of Inner Race on Shaft
- δ_H = Interference Fit of Outer Race in Housing

BEARING DIAMETER
EFFECT OF TIGHT FITS ON BEARING WIDTH
Normal Sections

The interference fit of either the cone or the cup increases the overall bearing width. For solid steel shafts and heavy sectioned steel housings, the increased bearing width for a single-row bearing is as follows. (Refer to diagram to the left.)

Bearing Width Increase for Single Cone

$$= 0.5 \left(\frac{K}{0.39} \right) \left(\frac{d}{d_o} \right) \delta_S$$

Bearing Width Increase for Single Cup

$$= 0.5 \left(\frac{K}{0.39} \right) \left(\frac{D_o}{D} \right) \delta_H$$

If the shaft or housing material is other than steel, consult your Timken representative.

Thin Wall Sections

Interference fits on thin-walled steel shafts and light-sectioned steel housings have a tendency to collapse the cone seat and stretch the cup seat, causing less change in bearing width than when used with solid shafts and heavy housings. The bearing width change due to tight fits on thin bearing seat sections is as follows. (Refer to diagram to the left.)

Bearing Width Increase for Single Cone

$$= 0.5 \left(\frac{K}{0.39} \right) \left\{ \frac{\left(\frac{d}{d_o} \right) \left[1 - \left(\frac{d_S}{d} \right)^2 \right]}{1 - \left(\frac{d_S}{d_o} \right)^2} \right\} \delta_S$$
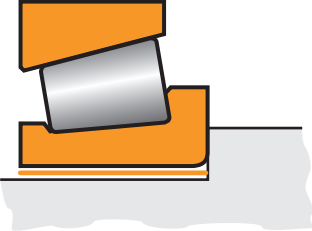

Bearing Width Increase for Single Cup

$$= 0.5 \left(\frac{K}{0.39} \right) \left\{ \frac{\left(\frac{D_o}{D} \right) \left[1 - \left(\frac{D}{D_H} \right)^2 \right]}{1 - \left(\frac{D_o}{D_H} \right)^2} \right\} \delta_H$$

These equations apply only to steel shafts and housings.

Aluminum housings min. fit of .001 inch per inch of cup O.D.
Magnesium housings min. fit of .0015 inch per inch of cup O.D.

A

FITTING PRACTICES - *continued*

Non-ferrous housings

Care should be taken when pressing cups into aluminum or magnesium housings to avoid metal pick up. This may result in unsatisfactory fits, backing, and alignment from debris trapped between the cup and backing shoulder. Preferably, the cup should be frozen or the housing heated, or both, during assembly. Also, a special lubricant may be used to ease assembly. In some cases, cups are mounted in steel inserts which are attached to the aluminum or magnesium housings. Table fits may then be used. Where the cup is fitted directly into an aluminum housing, it is suggested that a minimum tight fit of 1.0 μm per mm (0.0010 in. per in.) of cup outside diameter be used. For a magnesium housing, a minimum tight fit of 1.5 μm per mm (0.0015 in. per in.) of cup outside diameter is suggested.

Hollow shafts

In case of a thin section hollow shaft, the fits mentioned in the tables for industrial applications should be increased to avoid possible cone creeping under some load conditions.

Heavy-duty fitting practice

Where heavy-duty loads, shock loads or high speeds are involved, the heavy-duty fitting practice should be used, regardless of whether the cone seats are ground or unground. Where it is impractical to grind the shaft O.D. for the cone seats, the tighter heavy-duty fitting practice should be followed. In this case the turned shaft O.D. should not exceed a maximum surface finish of 3.2 μm (125 μin) arithmetic average.

The average interference cone fit for inch bearings above 76.2 mm (3 in.) bore should be 0.5 μm per mm (0.0005 in. per in.) of bearing bore. See inch fitting practice tables for cones with smaller bores. The minimum fit should not be less than 25 μm (0.0010 in.) tight. If the shaft diameter is held to the same tolerance as the bearing bore, use the average interference fit. For example, average interference fit between a 609.6 mm (24 in.) bore cone and shaft will be 305 μm (0.0120 in.). The fit range will be 305 μm (0.0120 in.) tight plus or minus the bearing bore tolerance. See metric fitting practice tables for heavy-duty metric cone fitting practice.

Double-row assemblies with double cups

Non-rotating double outer races of types TDO and TNA bearings are generally mounted with loose fits to permit assembly and disassembly (Fig. A-24). The loose fit also permits axial floating when the bearing is mounted in conjunction with an axially fixed (locating) bearing on the other end of the shaft. Double outer races types CD and DC can be pinned to prevent rotation in the housing. Fitting values can be taken from general industrial guidelines.

Fixed bearing   Floating bearing

Fig. A-24
Double-row bearing arrangement assembled with loose fit.

Bearing assemblies
SR, TNA, TNASW, TNASWE types

The tolerance and fits for bearing types SR, TNA, TNASW, and TNASWE are tabulated along with the other dimensions in the bearing tables.

CAUTION: Failure to use the specified fits may result in improper bearing setting. Reduced bearing performance or malfunction may occur. This may cause damage to machinery in which the bearing is a component. If interference fits are either greater or less than those specified, the mounted bearing setting will be other than intended.

FITTING PRACTICES - *continued*

SHAFT AND HOUSING FITS

RADIAL BALL AND CYLINDRICAL ROLLER BEARINGS

These charts are guidelines for specifying shaft and housing fits related to particular operating conditions.

[1] For solid shaft. See pages A61 for numerical values.
[2] Use j5 for accurate applications.
[3] Bearings with greater than nominal clearance must be used.

[4] Use k5 for accurate applications.
[5] Use m5 for accurate applications.
[6] C = Dynamic Load Rating.

[7] C$_e$ = Extended Dynamic Load Rating (Ball Bearings).
[8] Use j5 for accurate applications.

HOUSING				
Operating Conditions		**Examples**	**Housing Tolerance Symbol[1]**	**Outer Ring Displaceable Axially**
Outer Ring Rotating				
	Heavy loads with thin-wall housing	Crane support wheels Wheel hubs (roller bearings) Crank bearings	P6	No
	Normal to heavy loads	Wheel hubs (ball bearings) Crank bearings	N6	No
	Light loads	Conveyor rollers Rope sheaves Tension pulleys	M6	No
Indeterminate Load Direction				
	Heavy shock loads	Electric traction motors	M7	No
	Normal to heavy loads, axial displacement of outer ring not required.	Electric motors Pumps Crankshaft main bearings	K6	No, normally
	Light to normal loads, axial displacement of outer ring desired.	Electric motors Pumps Crankshaft main bearings	J6	Yes, normally
Outer Ring Stationary				
	Shock loads, temporary complete unloading	Heavy rail vehicles	J6	Yes, normally
All loads	One-piece housing	General applications Heavy rail vehicles	H6	Easily
	Radially split housing	Transmission drives	H7	Easily
	Heat supplied through shaft	Drier cylinders	G7	Easily

* Below this line, housing can either be one piece or split; above this line, a split housing is not suggested.

[1] Cast iron steel housing. See pages A61 to A72 for numerical values.
Where wider tolerances are permissible, P7, N7, M7, K7, J7 and H7 values may be used in place of P6, N6, M6, K6, J6, and H6 values respectively.

A

RADIAL BALL BEARINGS
ABEC 1 AND ABEC 3 BALL BEARINGS
Shaft and housing fits

The tables on the following pages show information supplemental to and coherent with that found on pages A125 through A139 as applied to ball bearings. Actual shaft and housing diameters are listed for ABEC 1, ABEC 3 and angular contact 7000WN Series. These suggestions can be used for most applications having light to normal loads. Shaft and housing fits for wide inner ring ball bearings are found on page A133.

ABEC 7 BALL BEARINGS
Shaft fits

As a general rule, it is suggested that the shaft size and tolerance for seating ABEC 7 super precision bearings be the same as the bearing bore thus producing an average line-to-line fit. For larger shaft sizes, the average fit increases to a slight interference.

EXAMPLE

Bore Size, Inches	Shaft Diameter, Inches	Resultant Mounting Fits, Inches	Average Fit
Max. 2.1654	Min. 2.1652	.0002 tight	line-to-line
Min. 2.1652	Max. 2.1654	.0002 loose	

HOUSING FITS

Under normal conditions of rotating shaft, the outer ring is stationary and should be mounted with a hand push or light tapping fit. Should the housing be the rotating member, the same fundamental considerations apply in mounting the outer race as in the case of an inner ring mounted on a rotating shaft.

As a general rule, the minimum housing bore dimensions for super precision bearings may be established as the same as the maximum bearing outside diameter. If the bearing O.D. tolerance is .0003 inch, the maximum housing bore should be established as .0003 inch larger than the minimum housing bore dimension.

EXAMPLE

Outside Diameter, Inches	Housing Bore, Inches	Resultant Mounting Fits, Inches	Average Fit Inches
Max. 3.5433	Min. 3.5433	.0000 tight	.0003 loose
Min. 3.5430	Max. 3.5436	.0006 loose	

On high-speed applications, it is extremely important that the floating bearing or pair can move axially to compensate for thermal changes. It cannot float laterally if restricted by a tight housing bore or by the radial expansion of the bearing itself. Cases involving unusual conditions should be submitted to your Timken representative for suggestions.

It is equally important that all shaft and housing shoulders be absolutely square and that the faces of the spacers be square and parallel.
Selective assembly

Under certain conditions it may be desirable to control fits more accurately without the added expense of using closer-tolerance bearings and mating parts. This can be accomplished by selective assembly of bearings, shafts and housings after they have been sized and grouped according to bores and outside diameters. Generally, however, it is more satisfactory for production and servicing to use closer shaft and housing tolerances with bearings having a higher degree of precision.

Bearings with coded bores and O.D.s are available on special order to facilitate this selective assembly process.

Shafts and housing fillets

The suggested shaft and housing fillet radii listed in the dimension tables of the product catalogs should be used to assure proper seating of the bearings against shaft and housing shoulders. The manufacturing tolerances on bearing corner radii are such that the corners will clear the cataloged fillet radii when the bearings are tightly seated against shoulders. Shaft and housing radii and shoulders should be free from nicks and burrs. Whenever possible, undercutting of bearing seats and adjacent shoulders per figure below is advisable to help avoid tapered bearing seats and assure clearing corners.

FITTING PRACTICES *- continued*

SHAFT AND HOUSING FITS RADIAL BALL BEARING
Shaft fits, ABEC 1, ABEC 3

Note: These tables are to be used for applications where only one ring (either inner or outer) has an interference fit with its shaft and housing. The guidelines for operating conditions covering these tables are found on page A123. In cases where interference fits are used for both rings, bearings with a special internal clearance may be required. Shaft diameter dimensions are for solid steel shafts. Consult your Timken representative when using hollow shafts.

[1] Mean fit loose. These sizes have plus bore tolerances.

A

FITTING PRACTICES - *continued*
SHAFT AND HOUSING FITS RADIAL BALL BEARING
Shaft fits, ABEC 1, ABEC 3

Note: These tables are to be used for applications where only one ring (either inner or outer) has an interference fit with its shaft and housing. The guidelines for operating conditions covering these tables are found on page A123. In cases where interference fits are used for both rings, bearings with a special internal clearance may be required. Shaft diameter dimensions are for solid steel shafts. Consult your Timken representative when using hollow shafts.

	SHAFT FITS, ABEC 1, ABEC 3																						
					These diameters result in shaft to bearing bore fit which closely conforms to k5 listed on pages A66 and A72								**These diameters result in shaft to bearing bore fit which closely conforms to g6 listed on pages A66 and A72**										
Basic Bearing Number	**Bore Tolerance**				**Shaft Rotating, Load Stationary or Shaft Stationary, Load Rotating**								**Shaft Stationary, Load Stationary or Shaft Rotating, Load Rotating**

SHAFT FITS, 7000WN

Note: These tables are to be used for applications where only one ring (either inner or outer) has an interference fit with its shaft and housing. The guidelines for operating conditions covering these tables are found on page A123. In cases where interference fits are used for both rings, bearings with a special internal clearance may be required. Shaft diameter dimensions are for solid steel shafts. Consult your Timken representative when using hollow shafts.

SHAFT FITS, 7000WN SINGLE ROW ANGULAR CONTACT BEARINGS									
				These diameters result in shaft to bearing bore fit which closely conforms to j5 listed on pages A67 and A72.

[2]400 Series are "specials," consult your Timken representative.

FITTING PRACTICES - *continued*

HOUSING FITS, ABEC 1, ABEC 3

A

Note: These tables are to be used for applications where only one ring (either inner or outer) has an interference fit with its shaft and housing. The guidelines for operating conditions covering these tables are found on page A123. In cases where interference fits are used for both rings, bearings with a special internal clearance may be required. Housing bore diameter dimensions are for steel materials. Consult your Timken representative when using other housing materials.

HOUSING FITS, ABEC 1, ABEC 3																				
					These diameters result in a bearing O.D. to housing bore fit which closely conforms to H6 beginning on A61								These diameters result in a bearing O.D. to housing bore fit which closely conforms to M7 listed on page A63

SHAFT AND HOUSING SHOULDERS

Shaft and housing shoulder diameters for radial roller and thrust ball and roller bearings are also found in the respective dimension tables. Shaft and housing shoulders for ball bearings are shown below.

RADIAL BALL BEARINGS

The preferred method of locating bearings on shafts and in housings is to provide accurate shoulders perpendicular to the shaft axis. Shoulders should be large enough to exceed the theoretical point of tangency between the corner radius and the face of the bearing, and small enough to permit bearing removal with proper pullers.

These tables give the suggested maximum and minimum shaft and housing shoulder diameters for the majority of applications. Where design limitations do not permit conformance to these suggested diameters, your Timken representative should be consulted.

Suggested shaft and housing fillet radii are listed in the dimensional tables of each product catalog and must be used to assure proper seating against shaft and housing shoulders.

Shaft and housing diameters for radial ball bearings are shown below and on the following two pages. For radial cylindrical, spherical and tapered roller bearings, refer to the respective dimension tables. Housing shoulders for wide inner ring bearings are shown on page A133.

Non-Standard Extra-Large

Mechani-Seal KL, KLD, KLL Types
Housing shoulder diameters of bearings with Mechani-Seals differ slightly from those of other types to allow for clearance between the external rotating member of the seal and the housing shoulder.

WIDE INNER RING BALL BEARINGS

When shafts are selected for use with wide inner ring bearings, a minimum slip fit is very desirable for the most satisfactory mounting. Special shaft limits are required in certain cases, and a variety of standard fits can be used, including a press fit. The suggested figures are noted below. In some applications, it may be permissible to use increased shaft tolerances. In such cases, applications should be forwarded to your Timken representative for complete suggestions.
Bearing bore tolerance:
½" - 2 ³⁄₁₆" = nominal to **+.013 mm** +.0005";
2 ¼" - 3 ³⁄₁₆" = nominal to **+.015 mm** +.0006";
3 ⁷⁄₁₆" - 3¹⁵⁄₁₆" = nominal to **+.018 mm** +.0007";

Shaft tolerances:
½" - 1 ¹⁵⁄₁₆" = nominal to **- .013 mm** -.0005";
2" - 3 ¹⁵⁄₁₆" = nominal to **-.025 mm** -.0010";

Bearings with Tapered Bore and Adapter Sleeve					
All loads		Applications in general	All diameters		See tables for Reduction of RIC on page A76.

[1] For solid steel shaft. See tables on pages A62-A72 for numerical value.

s4 fits

A centrifugal force load produces a rotating outer ring load and a stationary inner ring load, even though the inner ring rotates. This makes it desirable to fit the outer ring tight in the housing (using a P6 fit as shown on pages A63 and A69), and the inner ring loose on the shaft using an s4 fit as listed in the table. The standard W33 bearing with oil groove and oil holes can be used.

Note: The s4 fit designation as referenced on this page is a special fit tolerance developed by The Timken Company for this specific application. It DOES NOT conform to ISO standards similarly published as s4 preferred shaft fits.

S4 FITS

SHAFT AND HOUSING FITS
THRUST SPHERICAL ROLLER BEARING

Tolerances for housing bore and for shaft diameters are shown as variance from nominal bearing dimension. Data is shown in inches over millimeters. When application calls for thrust loads only, the housing must be relieved by $\frac{1}{16}$ in. on diameter so that no radial load is carried on the bearing. All tolerances are in number of micrometers (μm) and ten thousandths of an inch (.0001 in.).

SHAFT AND HOUSING FITS
THRUST TAPERED ROLLER BEARINGS

Tolerances for housing bore and shaft diameters are shown as variance from nominal bearing dimension. Data is shown in millimeters over inches. When one washer is piloted by the housing, sufficient clearances must be allowed at the outside diameter of the other washer as well as at the bore of both washers to prevent cross-loading of the rollers. For most applications, this clearance is approximately $\frac{1}{16}$ in. (**1.588 mm,** .0625 in.).

TTHD

- Rotating race O.D. must have a minimum radial clearance of 2.5 mm (0.1 in.)
- TTHD stationary race O.D. must have a minimum loose fit of 0.25 to 0.37 mm (0.01 to 0.015 in.)
- TTHDFL washer when stationary may be loose fit on its O.D. (same as the TTHD) or may be 0.025 to 0.076 mm (0.001 to 0.003 in.) tight.

A

BEARING SETTING

SETTING TAPERED ROLLER BEARINGS

Setting is defined as a specific amount of either endplay or preload. Establishing the setting at the time of assembly is an inherent advantage of tapered roller bearings. They can be set to provide optimum performance in almost any application. The following figure gives an example of the relationship between fatigue life and bearing setting. Unlike some types of anti-friction bearings, tapered roller bearings do not rely strictly on housing or shaft fits to obtain a certain bearing setting. One race can be moved axially relative to the other to obtain the desired bearing setting.
Relationship between bearing setting and fatigue life.

At assembly, the conditions of bearing setting are defined as:

- **Endplay** – An axial clearance between rollers and races producing a measurable axial shaft movement when a small axial force is applied - first in one direction, then in the other, while oscillating or rotating the shaft.

Internal clearance - "Endplay."

- **Preload** – An axial interference between rollers and races such that there is no measurable axial shaft movement when a small axial force is applied – in both directions, while oscillating or rotating the shaft.
- **Line-to-line** – A zero setting condition: the transitional point between endplay and preload.
Bearing setting obtained during initial assembly and adjustment is the cold or ambient bearing setting and is established before the equipment is subjected to service.

Bearing setting during operation is known as the operating bearing setting and is a result of changes in the ambient bearing setting due to thermal expansion and deflections encountered during service.

The ambient bearing setting necessary to produce the optimum operating bearing setting varies with the application. Application experience, or testing, generally permits the determination of optimum settings. Frequently, however, the exact relationship of ambient to operating bearing setting is an unknown and an educated estimate has to be made. To determine a suggested ambient bearing setting for a specific application, consult your Timken representative.

Generally, the ideal operating bearing setting is near zero to maximize bearing life. Most bearings are set with endplay at assembly to reach the desired near zero setting at operating temperature when mounted.

Standard mounting

Operating setting = mounted setting ± temperature effect ± deflection

Pre-set assemblies

Mounted EP or PL = Bench EP or Bench PL - effect of fits

Operating setting = mounted EP or PL (MEP or MPL) ± temperature effect ± deflection

The temperature and fit effects will depend upon the type of mounting, bearing geometry and size, shaft and housing size and material according to the following sketch:
Dimensions affecting the effects of temperature and fit.

BEARING SETTING - *continued*

TEMPERATURE EFFECT (IN A TWO-ROW MOUNTING)

Symbols used:

δ_S = interference fit of inner race on shaft

δ_H = interference fit of outer race in housing

K_n = K-factor for bearing #n

d = bearing bore diameter

d_o = mean inner race diameter

D = bearing outside diameter

D_o = mean outer race diameter

L = distance between bearing geometric center lines, mm (in.)

α = coefficient of linear expansion: $11 \times 10^{-6}/\,°C$ $(6.1 \times 10^{-6}/\,°F)$ for ferrous metal shaft and housing materials

d_S = shaft inside diameter

D_H = housing outside diameter

ΔT = temperature difference between shaft/inner race + rollers and housing/bearing outer race

DIRECT MOUNTING

$$\text{Thermal Lateral Loss} = \alpha\,\Delta T \left[\left(\frac{K_1}{0.39} \times \frac{D_{o1}}{2} \right) + \left(\frac{K_2}{0.39} \times \frac{D_{o2}}{2} \right) + L \right]$$

INDIRECT MOUNTING

$$\text{Thermal Lateral Loss} = \alpha\,\Delta T \left[\left(\frac{K_1}{0.39} \times \frac{D_{o1}}{2} \right) + \left(\frac{K_2}{0.39} \times \frac{D_{o2}}{2} \right) - L \right]$$

Note: Positive lateral loss is the amount of setting reduction or loss of endplay.

FIT EFFECT (SINGLE-ROW)

SOLID SHAFT/HEAVY SECTION HOUSING

Inner Race:

$$F = 0.5 \left(\frac{K}{0.39} \right)\left(\frac{d}{d_o} \right) \delta_S$$

Outer Race:

$$F = 0.5 \left(\frac{K}{0.39} \right)\left(\frac{D}{D_o} \right) \delta_H$$

Hollow shaft/thin wall section
Inner Race:

$$F = 0.5 \left(\frac{K}{0.39} \right)\left(\frac{d}{d_o} \right) \left[\frac{1 - \left(\frac{d_s}{d} \right)^2}{1 - \left(\frac{d_s}{d_o} \right)^2} \right] \delta_S$$

Note: These equations apply only to ferrous shaft and housing.

Outer Race:

$$F = 0.5 \left(\frac{K}{0.39} \right)\left(\frac{D_o}{D} \right) \left[\frac{1 - \left(\frac{D}{D_H} \right)^2}{1 - \left(\frac{D_o}{D_H} \right)^2} \right] \delta_H$$

SETTING METHODS FOR TAPERED ROLLER BEARINGS

Upper and lower limits of bearing setting value are determined by consideration of the following factors:

- Application type.
- Duty.
- Operational features of adjacent mechanical drive elements.
- Changes in bearing setting due to temperature differentials and deflections.
- Size of bearing and method of obtaining bearing setting.
- Lubrication method.
- Housing and shaft material.

The setting value to be applied during assembly will depend on any changes that may occur during operation. In the absence of experience with bearings of similar size and operating conditions, bearing setting range suggestions should be obtained from your Timken representative.

Direct mounting   Indirect mounting
Use the push-pull method (manual setting) to measure any axial endplay (used as reference) while rotating the shaft or the housing. Correct this reference value to the final required endplay or preload by changing the setting on the adjusting device. Fig. A-25 and A-26 are typical examples of manual setting applications.
Fig. A-25
Axial clearance (endplay).

Typical preset bearing assemblies.
TNA
TNASW

TNASWE

SR

SS

AP

TQO
If the application requires the use of multi-row bearing assemblies, preset bearings can be used (Fig. A-27). Various types of multi-row bearing combinations can be provided with spacers that are ground and custom-fitted to provide a bearing setting to meet the requirements of the application (Fig. A-28). Types SS, TDI, TDIT and TDO, listed in this publication, are examples.

Each matched assembly has an identifying serial number marked on each outer race, inner race and spacer. Some small preset assemblies are not marked with a serial number but their component parts are supplied as a boxed set.

A preset bearing assembly contains a specific fixed internal clearance (or preload) built in during manufacture. The value of this "setting" is referred to as "bench endplay" (BEP) or "bench preload" (BPL) and is normally determined by The Timken Company during the design stage of new equipment. Components from one bearing assembly are NOT interchangeable with similar parts from another.

Bearing settings for types TNA, TNASW, TNASWE (standard version) and SR bearings are obtained through close axial tolerance control and components from these assemblies are interchangeable for bearings having bore sizes under 305 mm (12 in.).

BEARING SETTING - *continued*

The Timken Company has developed various automated bearing setting techniques. The advantages of these techniques are:

- Reduced set-up time.
- Reduced assembly cost.
- Increased consistency and reliability of bearing settings.
- In most cases they can be applied to the assembly line for moderate and high volume production.

It is possible to select and adapt one of the following automated setting methods for a wide range of applications.
Fig. A-28
Bearing setting.

"Set-Right"™

This technique applies the laws of probability. The setting in the bearing is controlled by the radial and axial tolerances of the various components of the assembly.

"Acro-Set"™

The Acro-Set method is achieved through measurement of a shim or spacer gap with a specified set-up load applied. The correct shim or spacer dimension is then taken from a prepared chart or by a direct instrument reading. This technique is based on Hooke's law, which states that within the elastic limit, deformation or deflection is proportional to the load applied. It is applicable to either endplay or preload bearing settings.

"Torque-Set"™

The Torque-Set technique is a method of obtaining correct bearing settings by using low-speed bearing rolling torque as a basis for determining the amount of deformation or deflection of the assembly parts affecting bearing settings. This technique is applicable regardless of whether the final bearing setting is preload or endplay.

"Projecta-Set"™

The Projecta-Set technique is used to "project" an inaccessible shim or spacer gap to a position where it can easily be measured. This is achieved using a spacer and a gauging sleeve. The Projecta-Set technique is of most benefit on applications where the inner and outer races are an interference fit and therefore disassembly for adjustment is more difficult and time-consuming than with loose-fitting races.

Deciding which automated bearing setting technique should be used must be made early in the design sequence. It is necessary to review each application to determine the most economical method and necessary fixtures and tools. The final decision will be based on the size and weight of the unit, machining tolerances, production volume, access to retaining devices (locknuts, end plates, etc.) and available tools. Your Timken representative can assist in determining the best method to obtain the correct bearing setting.

DUPLEX SETS OF BALL BEARINGS AND PRELOADING

Two single-row ball bearings manufactured specially for use as a unit are known as a duplex bearing. It may be considered analogous to a double-row bearing having the same bore and outside diameter, but twice the single-row bearing width.

The main purpose of duplex bearings in an application is to achieve greater axial and radial rigidity than is possible with one single-row bearing. The extra "stiffness" in these bearings is obtained by "preloading." Preloading is incorporated into bearings by selective face grinding which is described in detail below.

Although angular contact bearings, such as the 7000, M-WI and MMWI types, are more commonly used in duplex arrangements, other types of bearings such as radial single-row open, shielded and sealed types, can be duplexed where required to meet specific conditions.

PRELOADING

Preloading to a predetermined value is accomplished by grinding a certain amount of material off inner or outer ring faces so that before mounting the two single bearings as a duplex pair, the faces on abutting sides are offset an amount equal to the deflection under the "preload."

When mounted, these faces are clamped together so that the bearings are subjected to an internal load caused by one bearing opposing the other. This "preloading" materially decreases subsequent deflection due to external loads applied to the clamped-up pair.

Timken has established, for each bearing size, standard preload levels which are considered proper for most duplex bearing applications. Special preloads can also be provided to satisfy

A

BEARING SETTING - *continued*

extreme requirements. For example, a heavily loaded, slow-speed rotating shaft may require heavier than normal preload in order to minimize deflection. It must be remembered, however, that although heavy preload provides slightly greater rigidity, it reduces bearing life and increases power consumption; therefore preload levels should be chosen with care.

The axial deflection of a bearing subject to thrust loading is based on Hertz's theories for elastic bodies in contact. The general expression is:

$$\delta = K \left(\frac{T^2}{nd^2} \right)^{1/3}$$

where δ = axial deflection
K = a constant based on bearing geometry
T = thrust load applied
n = number of balls
d = ball diameter

A typical axial deflection curve for an unpreloaded single-row angular contact bearing is shown in Figure A-29, as curve A. This curve represents the deflection characteristics of bearing "A" being subjected to thrust load T. The amount of deflection due to load T_1 is much greater than the increase in deflection caused by doubling the thrust load to T_2. This illustrates the non-linear deflection of a ball bearing.

Curves C_1 and C_2 show the deflection of bearings A and B flushmounted as a pair, shown below, with each bearing having a preload of T_1 and T_2 lbs., respectively. Comparing curves C_1 and C_2 with A shows the deflection of the preloaded pair is much less than that of a single unpreloaded bearing. This has been accomplished essentially by eliminating the "high deflection" points of curve A (from no load to T_1 or T_2 lbs.).

Curves B_1 and B_2 show the axial deflection of bearing B as mounted in Figure A-30 below from the preloaded conditions T_1 or T_2 to a no preload condition.

Preloading can be accomplished by the use of springs or spacer width adjustment, but your Timken representative should be consulted for design review.
Fig. A-29
Axial load-deflection curve of back-to-back mounted angular-contact bearings. Curve A is for Bearing A, B is for bearing B, and C_1 and C_2 are preload curves.

TYPICAL APPLICATIONS

Deep well pumps, marine propeller shafts, machine tool spindles, gear shafts, speed reducers, elevator worm drives, and similar applications often require the use of preloaded duplex bearings.

WIDTH TOLERANCES

To allow for face grinding of single bearings to specified preload for use in duplex pairs or other multiple bearing units, the inner and outer ring width tolerance of each bearing is greater than that for a standard single bearing as follows:

Bearing Bore mm		Width Tolerance ABEC	Width Tolerance ABEC
over	incl.	1,3	5,7,9
0	50	+.000" -.010"	+.000" -.010"
50	80	+.000" -.015"	+.000" -.010"
80	120	+.000" -.015"	+.000" -.015"
120	180	+.000" -.020"	+.000" -.015"
180	315	+.000" -.020"	+.000" -.020"
315	400	+.000" -.025"	+.000" -.025"

The inner and outer ring width tolerances of duplex pairs and other multiple bearing units equal the tolerances listed above times the number of bearings in the unit. For example, a duplex pair of 2MM9115 WI DUL bearings has an inner and outer ring width tolerance of .010 in x 2 or .020 in.

MOUNTINGS OF BALL BEARINGS

Duplex bearings may be used with spacers between the matching faces in order to increase the system's resistance to moment loading or to increase the system rigidity by using the bearings to minimize shaft deflection. Shaft and housing spacers should be ground together on a surface grinder to obtain exactly equal lengths to assure that the built-in preload will be maintained. Since duplex bearings provide a very rigid mounting, it is important that special attention be given to correct shaft and housing fits, squareness of shaft and housing shoulders and alignment of all mating parts. In order to prevent cramping of bearings and an abnormal increase in preload which could result in excessive heat and possible bearing damage, suggested shaft and housing tolerances must be followed, shaft and housing shoulders must be square, bearing spacers must be of equal length and all parts must be free of nicks and burrs.

Typical preloaded mountings are shown here.
Fig. A-30
Typical preload mountings

BEARING SETTING - *continued*
TYPICAL MOUNTINGS OF DUPLEX BEARINGS

Back-to-Back Mounting, DB or ("O")
(Contact angles diverging toward shaft centerline)

Before mounting, there is clearance between the two adjacent inner ring faces. After mounting, these faces are clamped together to provide an internal preload on each bearing. This arrangement is well suited for pulleys, sheaves and in other applications where there are overturning loads and also in all floating positions where thermal expansion of shaft occurs. It also provides axial and radial rigidity and equal thrust capacity in either direction when used in a fixed location. Back-to-back is the most commonly used of all duplex arrangements. Specify bearing number followed by suffix DU. Examples: 7207W-DU, 2MM207WI-DU. Also available as two single flush-ground bearings, e.g., 7207W SU (2 bearings).

Before Mounting   Mounted

Face-to-Face Mounting, DF or ("X")
(Contact angles converging toward shaft centerline)

Before mounting, there is clearance between the two adjacent outer ring faces. After mounting, these faces are clamped together between the housing shoulder and cover plate shoulder providing an internal preload on each bearing. This arrangement provides equal thrust capacity in either direction as well as radial and axial rigidity. Since the face-to-face mounting has inherent disadvantages of low resistance to moment loading and thermal instability, it should not be considered unless a significantly more convenient method of assembly or disassembly occurs from its use. Timken pairs for face-to-face mounting should be ordered as DU. Examples: 7212W-DU, 2M212WI-DU. Also available as two single flush-ground bearings, e.g., 7212W SU (two bearings).

Before Mounting   Mounted

Tandem Mounting, DT

Before mounting, the inner ring faces of each bearing are offset from the outer ring faces. After mounting, when a thrust load is applied equal to that of twice the normal preload, the inner and outer ring faces are brought into alignment on both sides. This arrangement provides double thrust capacity in one direction only. More than two bearings can be used in tandem if additional thrust capacity is required. Timken pairs for tandem mounting should be specified as DU. Examples: 7205W-DU, 2M205WI-DU. Also available as two single flush-ground bearings with suffix SU, e.g., 7210W SU (two bearings).

Before Mounting   Mounted

Other Mountings

Flush ground (DU) pairs may be mounted in combination with a single flush-ground bearing as a "triplex" (TU) set shown below illustrates a "quadruplex" (QU) set where three bearings in tandem are mounted back-to-back with a single bearing. These arrangements provide high capacity in one direction and also a positively rigid mounting capable of carrying a moderate amount of reverse thrust.

TU   QU

A
LUBRICATION AND SEALS

LUBRICATION

To help maintain a rolling bearing's anti-friction characteristics, lubrication is needed to:

- Minimize rolling resistance due to deformation of the rolling elements and raceway under load by separating the mating surfaces.
- Minimize sliding friction occurring between rolling elements, raceways and cage.
- Transfer heat (with oil lubrication).
- Protect from corrosion and, with grease lubrication, from contaminant ingress.

Modern lubricants do this very effectively, although in many applications the means by which they accomplish this are extremely complex and not completely understood. Because the principles involved with lubricating rolling element bearings are complex and do not have to be known to employ lubricants successfully, this discussion will stress the practical rather than the theoretical aspects of lubrication.

LUBRICATION SELECTION

The wide range of bearing types and operating conditions precludes any simple, all-inclusive statement or guideline allowing the selection of the proper lubricant. At the design level, the first consideration is whether oil or grease is best for the particular operation. The advantages of oil and grease are outlined in the table below. When heat must be carried away from the bearing, oil must be used. It is nearly always preferred for very high-speed applications. For limiting speeds of grease and oil-lubricated bearings, refer to the section entitled "Speed, Heat and Torque" section.

ADVANTAGES OF OIL AND GREASE	
OIL	**GREASE**
Carries heat away from the bearings	Simplifies seal design and acts as a sealant
Carries away moisture and particulate matter	Permits prelubrication of sealed or shielded bearings
Easily controlled lubrication	Generally requires less frequent lubrication

LUBRICANT ADDITIVES

Additives are materials, usually chemicals, that improve specific properties when added to lubricants. Additives, when properly formulated into a lubricant, can increase lubricant life, provide greater resistance to corrosion, increase load-carrying capacity and enhance other properties. Additives are very complex and should not be added indiscriminately to lubricants as a cure-all for all lubrication problems.

The more common lubricant additives include:

- Oxidation inhibitors for increasing lubricant service life.
- Rust or corrosion inhibitors to protect surfaces from rust or corrosion.

- Demulsifiers to promote oil and water separation.
- Viscosity-index improvers to decrease viscosity sensitivity to temperature change.
- Pour-point depressants to lower the pouring point at low temperatures.
- Lubricity agents to modify friction.
- Antiwear agents to retard wear.
- Extreme pressure (EP) additives to prevent scoring under boundary-lubrication conditions.
- Detergents and dispersants to maintain cleanliness.
- Antifoam agents to reduce foam.
- Tackiness agents to improve adhesive properties.

Inorganic additives such as molybdenum disulphide, graphite, and zinc oxide are sometimes included in lubricants. In most tapered roller bearing applications, inorganic additives are of no significant benefit; conversely, as long as the concentration is low and the particle size small, they are not harmful.

Recently, the effects of lubricant chemistry on bearing life (as opposed to the purely physical characteristics) have received much emphasis. Rust, oxidation, extreme pressure and anti-wear additive packages are widely used in engine and gear oils. Fatigue testing has shown these additives may, depending on their chemical formulation, concentration and operating temperature, have a positive or negative impact on bearing life.

Consult your Timken representative for more information regarding lubricant additives.

GUIDANCE FOR OIL/GREASE SELECTION
Oil lubrication

Oils used for bearing lubrication should be high-quality, non-oxidizing mineral oils or synthetic oils with similar properties. Selection of the proper type of oils depends on bearing speed, load, operating temperature and method of lubrication.

Some features and advantages of oil lubrication, in addition to the above, are as follows:

- Oil is a better lubricant for high speeds or high temperatures. It can be cooled to help reduce bearing temperature.
- With oil, it is easier to handle and control the amount of lubricant reaching the bearing. It is harder to retain in the bearing. Lubricant losses may be higher than with grease.
- As a liquid, oil can be introduced to the bearing in many ways, such as drip-feed, wick-feed, pressurized circulating systems, oil-bath or air-oil mist. Each is suited to certain types of applications.
- Oil is easier to keep clean for recirculating systems. Oil may be introduced to the bearing housing in many ways.

LUBRICATION AND SEALS - *continued*

The most common systems are:

- **Oil bath.** The housing is designed to provide a sump through which the rolling elements of the bearing will pass. Generally, the oil level should be no higher than the center point of the lowest rolling element. If speed is high, lower oil levels should be used to reduce churning. Gages or controlled elevation drains are used to achieve and maintain the proper oil level.

- **Circulating system.** This system has the advantages of:
  - An adequate supply of oil for both cooling and lubrication.
  - Metered control of the quantity of oil delivered to each bearing.
  - Removal of contaminants and moisture from the bearing by flushing action.
  - Suitability for multiple bearing installations.
  - Large reservoir, which reduces deterioration. Increased lubricant life provides economical efficiency.
  - Incorporation of oil filtering devices.
  - Positive control to deliver the lubricant where needed.

  A typical circulating oil system consists of an oil reservoir, pump, piping and filter. A cooler may be required.

- **Oil-mist lubrication.** Oil-mist lubrication systems are used in high-speed, continuous operation applications. This system permits close control of the amount of lubricant reaching the bearings. The oil may be metered, atomized by compressed air and mixed with air, or it may be picked up from a reservoir using a venturi effect. In either case, the air is filtered and supplied under sufficient pressure to assure adequate lubrication of the bearings. Control of this type of lubrication system is accomplished by monitoring the operating temperatures of the bearings being lubricated. The continuous passage of the pressurized air and oil through the labyrinth seals used in the system prevents the entrance of contaminants from the atmosphere to the system. The successful operation of this type of system is based upon the following factors: proper location of the lubricant entry ports in relation to the bearings being lubricated, avoidance of excessive pressure drops across void spaces within the system, the proper air pressure and oil quantity ratio to suit the particular application, and the adequate exhaust of the air-oil mist after lubrication has been accomplished. To ensure "wetting" of the bearings and to prevent possible damage to the rolling elements and races, it is imperative that the oil mist system be turned on for several minutes before the equipment is started. The importance of "wetting" the bearing before starting cannot be overstated and has particular significance for equipment that has been idled for extended periods of time.

WARNING

Proper maintenance and handling practices are critical. Failure to follow installation instructions and to maintain proper lubrication can result in equipment failure, creating a risk of serious bodily harm.

OIL LUBRICATION GUIDELINES
Oil lubrication

Lubricating oils are commercially available in many forms for automotive, industrial, aircraft and other uses. Oils are classified as either petroleum types (refined from crude oil) or synthetic types (produced by chemical synthesis).

Petroleum oils

Petroleum oils are used for nearly all oil-lubricated applications of Timken bearings. These oils have physical and chemical properties that can help in the selection of the correct oil for any bearing application.

Synthetic oils

Synthetic oils cover a broad range of categories, and include polyalphaolefins, silicones, polyglycols, and various esters. In general, synthetic oils are less prone to oxidation and can operate at extreme hot or cold temperatures. Physical properties such as pressure-viscosity coefficients tend to vary between oil types and caution should be used when making oil selections.

The polyalphaolefins (PAO) have a hydrocarbon chemistry, which parallel petroleum oil both in their chemical structures and pressure-viscosity coefficients. Therefore, PAO oil is mostly used in the oil-lubricated applications of Timken bearings when severe temperature environments (hot and cold) are encountered or when extended lubricant life is required. The silicone, ester and polyglycol oils have an oxygen based chemistry that is structurally quite different from petroleum oils and PAO oils. This difference has a profound effect on its physical properties where pressure-viscosity coefficients can be lower compared to mineral and PAO oils. This means that these types of synthetic oils may actually generate a smaller EHD film thickness than a mineral or PAO oil of equal viscosity at operating temperature. Reductions in bearing fatigue life and increases in bearing wear could result from this reduction of lubricant film thickness.

SELECTION OF OILS

The selection of oil viscosity for any bearing application requires consideration of several factors: load, speed, bearing setting, type of oil, and environmental factors. Since viscosity varies inversely with temperature, a viscosity value must always be stated with the temperature at which it was determined. High viscosity oil is used for low-speed or high-ambient temperature applications. Low viscosity oil is used for high-speed or low-ambient temperature applications.

Approximate Temperature Limits For Oils		
Petroleum	149° C	300° F
Super Refined Petroleum	177° C	350° F
Synthetic Hydrocarbon	204° C	400° F
Synthetic Esters	204° C	400° F
Silicones	260° C	500° F
Polyphenylether	288° C	550° F
Perfluorinated	316° C	600° F

LUBRICATION AND SEALS - *continued*

CLASSIFICATION

There are several classifications of oils based on viscosity grades. The most familiar are the Society of Automotive Engineers (SAE) classifications for automotive engine and gear oils. The American Society for Testing and Materials (ASTM) and the International Organization for Standardization (ISO) have adopted standard viscosity grades for industrial fluids. Fig. A-31 shows the viscosity comparisons of ISO/ASTM with SAE classification systems at 40° C.
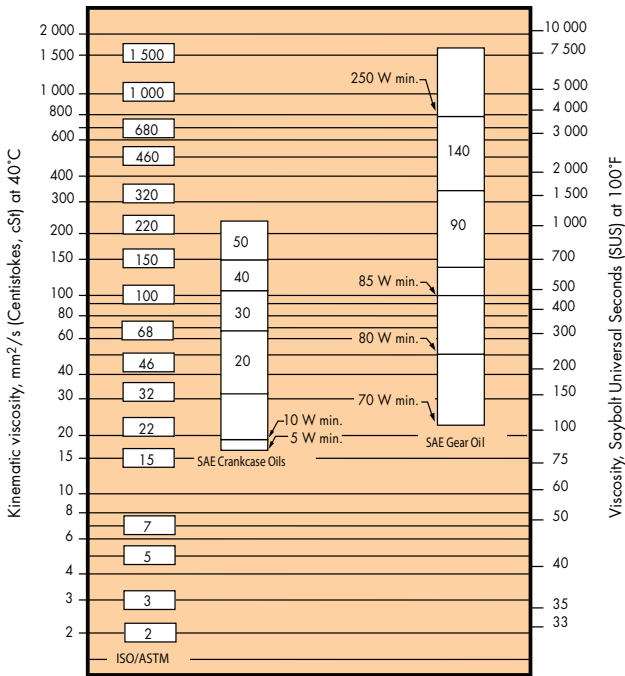

Fig. A-31
Viscosity classification comparison between ISO/ASTM grades (ISO 3448/ASTM D2442) and SAE grades (SAE J 300-80 for crankcase oils, SAE J 306-81 for axle and manual transmission oils).

The figure below can be used to predict the oil's kinematic viscosity versus temperature (use base oil for grease).

TEMPERATURE VS. KINEMATIC VISCOSITY
Fig. A-31a

TYPICAL OIL LUBRICATION GUIDELINES

In this section, the properties and characteristics of lubricants for typical tapered roller bearing applications are listed. These general characteristics have resulted from long successful performance in these applications.

General purpose rust and oxidation lubricating oil

General purpose rust and oxidation (R&O) inhibited oils are the most common type of industrial lubricant. They are used to lubricate Timken bearings in all types of industrial applications where conditions requiring special considerations do not exist.

**SUGGESTED GENERAL PURPOSE
R&O LUBRICATING OIL PROPERTIES**

Base stock	Solvent refined, high viscosity-index petroleum oil
Additives	Corrosion and oxidation inhibitors
Viscosity index	80 min.
Pour point	-10° C max.
Viscosity grades	ISO/ ASTM 32 through 220

Some low-speed and/or high-ambient temperature applications require the higher viscosity grades, and high-speed and/or low-temperature applications require the lower viscosity grades.

Industrial extreme pressure (EP) gear oil

Extreme pressure gear oils are used to lubricate Timken bearings in all types of heavily loaded industrial equipment. They should be capable of withstanding heavy loads including abnormal shock loads common in heavy-duty equipment.

SUGGESTED INDUSTRIAL EP GEAR OIL PROPERTIES

Base stock	Solvent refined, high viscosity index petroleum oil
Additives	Corrosion and oxidation inhibitors. Extreme pressure (EP) additive* - 15.8 kg (35 lb) min. "OK" Timken load rating
Viscosity index	80 min.
Pour point	-10° C max.
Viscosity grades	ISO/ ASTM 100, 150, 220, 320, 460

* ASTM D 2782

Industrial EP gear oils should be composed of a highly refined petroleum oil-based stock plus appropriate inhibitors and additives. They should not contain materials that are corrosive or abrasive to bearings. The inhibitors should provide long-term protection from oxidation and protect the bearing from corrosion in the presence of moisture. The oils should resist foaming in service and have good water separation properties. An EP additive protects against scoring under boundary-lubrication conditions. The viscosity grades suggested represent a wide range. High temperature and/or slow-speed applications generally require the higher viscosity grades. Low temperatures and/or high speeds require the use of lower viscosity grades.

LUBRICATION AND SEALS - *continued*
LUBRICATING GREASES
Definition

According to the ASTM definition, lubricating grease is a "solid to semi-fluid product of the dispersion of a thickening agent in a liquid lubricant; other ingredients imparting special properties may be included." If this definition were applied in the manner a chemist would use to illustrate a chemical reaction, the composition of a grease could be described by the formula below.

Fluids	+Thickening Agents	+Special Ingredients	=Lubricating Grease

Mineral Oils
Esters
Organic
  Esters
Glycols
Silicones
	Soaps
	  Lithium, Sodium
	  Barium, Calcium
	  Strontium
	Non-Soap (Inorganic)
	  Microgel (Clay)
	  Carbon Black
	  Silica-gel
	Non-Soap (Organic)
	  Urea compounds
	  Terepthlamate
	  Organic Dyes
		Oxidation Inhibitors
		Rust Inhibitors
		VI Improver
		Tackiness
		Perfumes
		Dyes
		Metal Deactivator	

At this time, there is no known universal anti-friction bearing grease. Each individual grease has certain limiting properties and characteristics.

Synthetic lubricating fluids, such as esters, organic esters and silicones, are used with conventional thickeners or chemical additives to provide greases capable of performing over an extremely wide range of temperatures, from as low as -73° C (-100° F) to a high of 288° C (550° F).

The successful use of lubricating grease in roller bearings depends on the physical and chemical properties of the lubricant pertaining to the bearing, its application, installation and general environmental factors. Because the choice of a lubricating grease for a particular bearing under certain service conditions is often difficult to make, your Timken representative should be consulted for proper suggestions.

Grease lubrication

The simplest lubrication system for any bearing application is grease. Conventionally, greases used in Timken bearing applications are petroleum oils of some specific viscosity that are thickened to the desired consistency by some form of metallic soap. Greases are available in many soap types such as sodium, calcium, lithium, calcium-complex and aluminium-complex. Organic and inorganic type non-soap thickeners also are used in some products.

Soap type

Calcium greases have good water resistance. Sodium greases generally have good stability and will operate at higher temperatures, but they absorb water and cannot be used where moisture is present. Lithium, calcium-complex and aluminium-complex greases generally combine the higher temperature properties and stability of sodium grease with the water resistance of calcium grease. These greases are often referred to as multi-purpose greases since they combine the two most important lubricant advantages into one product.

CHARACTERISTICS AND OPERATING ENVIRONMENTS

Listed below are the general characteristics of prominent rolling bearing greases.

Thickener	Typical Dropping PT		Usable** Temperature		Typical Water Resistance
	C	F	C	F	
Sodium Soap	260+	500+	121	250	Poor
Lithium Soap	193	380	104	220	Good
Polyurea	238	460	149	300	Excellent
Lithium Complex Soap	260+	500+	163	325	Good

** Continuous operation with no relubrication. Depending upon the formulation the service limits may vary. The usable limit can be extended significantly with relubrication.

Polyurea as a thickener for lubricating fluids is one of the most significant lubrication developments in more than 30 years. Polyurea grease performance in a wide range of bearing applications is outstanding, and in a relatively short time it has gained acceptance as a factory-packed lubricant for ball bearings.

Consistency

Greases may vary in consistency from semifluids hardly thicker than a viscous oil, to solid grades almost as hard as a soft wood.

Consistency is measured by a penetrometer, in which a standard weighted cone is dropped into the grease. The distance the cone penetrates (measured in tenths of a millimeter in a specific time) is the penetration number.

The National Lubricating Grease Institute (N.L.G.I.) classification of grease consistency is shown below:

NLGI Grease Grades	Penetration Number
0	355-385
1	310-340
2	265-295
3	220-250
4	175-205
5	130-160
6	85-115

Grease consistency is not fixed; it normally becomes softer when sheared or "worked." In the laboratory this "working" is accomplished by forcing a perforated plate up and down through a closed container of grease. This "working" does not compare with the violent shearing action that takes place in a ball bearing and does not necessarily correlate with actual performance.

A

LUBRICATION AND SEALS - *continued*

Low Temperatures

Starting torque in a grease-lubricated ball bearing at low temperatures can be critical. Some greases may function adequately as long as the bearing is operating, but resistance to initial movement is such that the starting torque is excessive. In certain smaller machines, starting is an impossibility when very cold. Under such operating circumstances, the greases containing low-temperature characteristic oils are generally required.

If the operating temperature range is wide, synthetic fluid greases offer definite advantages. Greases are available to provide very low starting and running torque at temperatures as low as -73° C (-100° F). In certain instances, these greases perform better in this respect than oil.

An important point concerning lubricating greases is that the starting torque is not necessarily a function of the consistency or the channel properties of the grease. It appears to be more a function of the individual properties of the particular grease and is difficult to measure. Experience alone will indicate whether one grease is superior to another.

High Temperatures

The high temperature limit for modern grease is generally a function of the thermal and oxidation stability of the fluid and the effectiveness of the oxidation inhibitors. The graph, to the right, was prepared using military-specification greases to illustrate the thermal limitations of mineral oil, ester, silicone, and fluorinated ether greases. The limits as shown apply only to prelubricated bearings or to applications where relubrication is not possible. Where provisions have been made for relubrication, the temperature limits may be extended provided the interval between cycles is reduced accordingly.

A rule of thumb, developed from years of testing grease-lubricated bearings, indicates that grease life is halved for every 10° C (18° F) increase in temperature. For example, if a particular grease is providing 2,000 hours of life at 90° C (194° F) by raising the temperature to 100° C (212° F) reduction in life to approximately 1,000 hours would result. On the other hand, 4,000 hours could be expected by lowering the temperature to 80° C (176° F).

It becomes obvious that the reactions started by the normal reaction of lubricant with oxygen increases rapidly at higher temperatures. The lubricants undergo a series of chemical reactions, that ultimately result in the development of viscous or hard residues that interfere with the operation of the bearing.

Thermal stability, oxidation resistance, and temperature limitations must be considered when selecting greases for high-temperature applications. In non-relubricatable applications, highly refined mineral oils or chemically stable synthetic fluids are required as the oil component of greases for operation at temperatures above 121° C (250° F).

Approximate Temperature Limits For Grease Thickeners		
Soaps	121° C	250° F
Complexes	177° C	350° F
Polyureas	177° C	350° F
Non-soap	>260° C	>500° F

WARNING

Mixing grease types can cause the lubricant to become ineffective, which can result in equipment failure, creating a risk of serious bodily harm.

A

LUBRICATION AND SEALS - *continued*

WET CONDITIONS

Water and moisture can be particularly conducive to bearing damage. Lubricating greases may provide a measure of protection from this contamination. Certain greases, the calcium, lithium and non-soap type, for example, are highly water-resistant. However, these greases exhibit poor rust preventative characteristics unless properly inhibited.

Sodium-soap greases emulsify with small amounts of moisture that may be present and prevent the moisture from coming in contact with the bearing surfaces. In certain applications, this characteristic may be advantageous; however, emulsions are generally considered undesirable.

Many bearing applications require lubricants with special properties or lubricants formulated specifically for certain environments, such as:

- Friction Oxidation (Fretting Corrosion).
- Chemical and Solvent Resistance.
- Food Handling.
- Quiet Running.
- Space and/or Vacuum.
- Electrical Conductivity.

For assistance with these or other areas requiring special lubricants, consult your Timken representative.

CONTAMINATION

Abrasive particles

When tapered roller bearings operate in a clean environment, the primary cause of damage is the eventual fatigue of the surfaces where rolling contact occurs. However, when particle contamination enters the bearing system, it is likely to cause damage such as bruising, which can shorten bearing life.

When dirt from the environment or metallic wear debris from some component in the application is allowed to contaminate the lubricant, wear can become the predominant cause of bearing damage. If, due to particle contamination of the lubricant, bearing wear becomes significant, changes will occur to critical bearing dimensions that could adversely affect machine operation.

Bearings operating in a contaminated lubricant exhibit a higher initial rate of wear than those running in an uncontaminated lubricant. But, with no further contaminant ingress, this wear rate quickly diminishes as the contamination particles are reduced in size as they pass through the bearing contact area during normal operation.

Water

Either dissolved or suspended water in lubricating oils can exert a detrimental influence on bearing fatigue life. Water can cause bearing etching that also can reduce bearing fatigue life. The exact mechanism by which water lowers fatigue life is not fully understood. It has been suggested that water enters microcracks in the bearing races that are caused by repeated stress cycles. This leads to corrosion and hydrogen embrittlement in the microcracks, reducing the time required for these cracks to propagate to an unacceptable size spall.

Water-base fluids such as water glycol and invert emulsions also have shown a reduction in bearing fatigue life. Although water from these sources is not the same as contamination, the results support the previous discussion concerning water-contaminated lubricants.

The following chart gives a good idea of the influence of water on bearing life. Based on Timken Technology tests, it was determined that water content of 0.01 percent (100 parts per million) or less, had no effect on bearing life. Greater amounts of water in the oil will reduce bearing life significantly.

LIFE REDUCTION WITH WATER CONTAMINATION

A
LUBRICATION AND SEALS - *continued*

GREASES - APPLICATIONS AND LUBRICATING METHODS

Grease lubrication is generally applicable to the following conditions, and features low-to-moderate speed applications within operating temperature limits of the grease:

- Easily confined in the housing. This is important in the food, textile and chemical industries.
- Bearing enclosure and seal design simplified.
- Improves the efficiency of external mechanical seals to give better protection to the bearing.
- Successfully used for integrally-sealed, prelubricated ball bearings.

Advantages of prelubricated ball bearings

Prelubricated shielded and sealed bearings are extensively used with much success in applications where:

- Grease might be injurious to other parts of the mechanism.
- Cost and space limitations preclude the use of a grease filled housing.
- Housings cannot be kept free of dirt and grit, water or other contaminants.
- Relubrication is impossible or would be a hazard to satisfactory use.

Prelubricated Timken bearings are prepacked with greases that have chemical and mechanical stability and have demonstrated long life characteristics in rotating bearings. Greases are filtered several times to remove all harmful material and accurately metered so that each bearing receives the proper amount of grease.

GREASE LUBRICATION FOR BEARING / HOUSING ASSEMBLIES

Polyurea and lithium-based greases are normally preferred for general purpose bearing lubrication and are advantageous in high moisture applications. Both greases have good water-resistant characteristics. For temperature ranges of standard greases, see chart below.

The grease must be carefully selected with regard to its consistency at operating temperature. It should not exhibit thickening, separation of oil, acid formation or hardening to any marked degree. It should be smooth, non-fibrous and entirely free from chemically active ingredients. Its melting point should be considerably higher than the operating temperature.

Frictional torque is influenced by the quantity and the quality of lubricant present. Excessive quantities of grease cause churning. This results in excessive temperatures, separation of the grease components, and breakdown in lubrication values. In normal speed applications, the housings should be kept approximately one-third to one-half full.

Only on low speed applications may the housing be entirely filled with grease. This method of lubrication is a safeguard against the entry of foreign matter, where sealing provisions are inadequate for exclusion of contaminants or moisture.

During periods of non-operation, it is often wise to completely fill the housings with grease to protect the bearing surfaces. Prior to subsequent operation, the excess grease should be removed and the proper level restored.

Applications utilizing grease lubrication should have a grease fitting and a vent at opposite ends of the housing near the top. A drain plug should be located near the bottom of the housing to allow purging of the old grease from the bearing.

Relubricate at regular intervals to prevent damage to the bearing. Relubrication intervals are difficult to determine. If plant practice or experience with other applications is not available, consult your lubricant supplier.

STANDARD LUBRICATION - TIMKEN BALL BEARINGS

Bearing Type	Grease Type	Grease Temperature Range
Radial Bearings (Double shielded and Single and Double Sealed)	Polyurea thickener Petroleum oil	-30° to +275° F
Wide Inner Ring Bearings (Contact Seal Types)	Polyurea thickener Petroleum oil	-30° to +275° F
Wide Inner Ring Bearings (Labyrinth Seal Types)	Synthetic thickener Synthetic hydrocarbon fluid	-65° to +325° F

Note: Open type bearings and single shielded types are NOT prelubricated. They have a rust preventative coating only and must be lubricated by the customer or end-user before operation.

LUBRICATION AND SEALS - *continued*

Multi-purpose industrial grease

These are typical of greases that can be used to lubricate many Timken bearing applications in all types of standard equipment. Special consideration should be given to applications where speed, load, temperature or environmental conditions are extreme.

Timken Multi-Use Lithium Grease	
Soap Type:	Lithium
Consistency:	NLGI No. 1 or No. 2
Additives:	Corrosion and oxidation inhibitors
Base Oil:	Petroleum/Mineral
Base Oil Viscosity at 40° C:	145.6
Pour Point:	-18° C max.
Color:	Light Brown

General purpose industrial grease should be a smooth, homogeneous and uniform, premium-quality product composed of petroleum oil, a thickener, and appropriate inhibitors. It should not contain materials that are corrosive or abrasive to tapered roller bearings. The grease should have excellent mechanical and chemical stability and should not readily emulsify with water. The grease should contain inhibitors to provide long-term protection against oxidation in high-performance applications and protect the bearings from corrosion in the presence of moisture.

The suggested base oil viscosity covers a fairly wide range. Lower viscosity products should be used in high-speed and/or lightly loaded applications to minimize heat generation and torque. Higher viscosity products should be used in moderate- to low-speed applications and under heavy loads to maximize lubricant film thickness.

Mineral grease

When conventional (mineral) greases are used, the rib speed should be limited to 5 m/s. This limit can be increased under pure radial loads up to 13 m/s provided that the bearings remain in endplay under all operating conditions. Generally, No. 2 consistency greases are used with medium- to low-viscosity base oils.

$$V_{mg} = f_{mg} \times V = f_{mg} \times [\frac{\pi}{4} \times T \times (D^2 - d^2) \times 10^{-3} - \frac{M}{7.8 \times 10^{-3}}] \text{ (cm}^3)$$

where:

f_{mg}	= factor depending on speed: $0.3 < f_{mg} < 0.5$	
V	= free volume of the bearing	(cm³)
T	= overall bearing width	(mm)
D	= cup outer diameter	(mm)
d	= cone bore	(mm)
M	= bearing weight	(kg)

Synthetic grease fill

The use of "low torque" greases (or synthetic greases) can be considered for rib speeds over 2,560 fpm (13 m/s), up to maximum of 4,920 fpm (25 m/s). Experience has shown that stabilized temperatures, around 15° C to 20° C (60° F to 68° F) above ambient, can be obtained at the maximum permissible speed.

The following procedures must be respected to achieve the above performance:

- Very small initial quantity of grease is applied to prevent excessive churning.
- Initial run-in period to evacuate unnecessary grease from the bearing.
- Good spindle design to retain grease around the bearings.
- Efficient sealing to protect against external contamination.

$$V_{sg} = f_{sg} \times V = f_{sg} \times [\frac{\pi}{4} \times T \times (D^2 - d^2) \times 10^{-3} - \frac{M}{7.8 \times 10^{-3}}] \text{ (cm}^3)$$

where:

f_{sg} = factor depending on speed: $0.15 < f_{sg} < 0.3$

LUBRICATION AND SEALS - *continued*
Filling a bearing with synthetic grease

When using synthetic greases, the limiting factor is the "lubrication for life" concept (without re-greasing).

A normal way to fill the bearing with grease is to do it by hand before heating and fitting the components. For the cone, the free volume corresponding to the first third of the rollers, starting from their large end, is filled with grease; an additional quantity is provided below the cage. For the cup, a thin film of grease is spread all around the race.

Grease lubrication of spindle bearings is generally preferred by machine tool builders over oil circulation lubrication due to its simplicity and low heat generation. For high loads or high speeds, circulating oil is probably the most widely used method because of its capability to remove heat from the spindle.

RE-GREASING CYCLE

The two primary considerations that determine the re-greasing cycle on any application are operating temperature and sealing efficiency. Obviously, seal leakage will dictate frequent relubrication. Every attempt should be made to maintain seals at peak efficiency. It is generally stated that the higher the temperature, the more rapidly the grease oxidizes. Grease life is reduced by approximately half for every 10° C rise in temperature.

The higher the operating temperature, the more often the grease must be replenished. In most cases, experience in the specific application will dictate the frequency of lubrication.

A

LUBRICATION AND SEALS - *continued*

Timken application specific lubricants have been developed by leveraging our knowledge of tribology and anti-friction bearings and how these two elements affect overall system performance. Timken lubricants help bearings and related components operate effectively in demanding industrial operations. High-temperature, anti-wear and water-resistant additives offer superior protection in challenging environments. This chart is intended to provide an overview of the Timken greases available for general applications. Contact your local Timken representative for a more detailed publication on Timken lubrication solutions.

LUBRICATION SELECTION GUIDE

Environment		*Application*
High Wear • Moderate Loads Moderate Speeds Moderate Temperatures	Timken Premium All Purpose Industrial Grease	Agriculture • Bushings/Ball Joints Truck and Auto Wheel Bearings Heavy Duty Industrial
High Speeds • Light Loads Moderate Temperatures Moderate Water	Timken Ball Bearing Electric Motor Grease	Alternators • Generators Electric Motors • Fans/Pumps
Extreme Heat • Heavy Loads High Sliding Wear Dirty Environments Slow Speeds • Shock Loading	Timken Construction and Off-Highway Grease	Agriculture/Mining • Cement Plants Construction/Off Road • Rock Quarry Earth Moving Equipment Fleet Equipment • Heavy Industry Pivot Pins/Splined Shafts
Wet and Corrosive Conditions Quiet Environments • Light Loads Moderate to High Speeds Moderate Temperatures	Timken Ball Bearing Pillow Block Grease	Lightly Loaded Pillow Blocks Idler Pulleys • Oven Conveyors Chemical Manufacture Noise-Sensitive Applications
Corrosive Media • Extreme Heat Heavy Loads • Wet Conditions Slow to Moderate Speeds	Timken Mill Grease	Aluminum Mills • Paper Mills Steel Mills • Offshore Rigs Power Generation
Incidental Food Contact Hot and Cold Temperatures Moderate to High Speeds Medium Loads	Timken Food Safe Grease	Food and Beverage Industries Pharmaceuticals
Extreme Low and High Temperatures Severe Loads Corrosive Media Slow to Moderate Speeds	Timken Synthetic Industrial Grease	Wind Energy Main Bearing Pulp and Paper Machines General Heavy Industry Marine Applications Centralized Grease Systems
Ultra-High Speeds Extreme Low Temperatures	Timken Ultra-High Speed Spindle Grease	Machine Tools Associated with: Grinding • Drilling • Turning Milling • Lathes
Moderate Speeds Light to Moderate Loads Moderate Temperatures Moderate Water	Timken Multi-Use Lithium Grease	General Industrial Applications Pins and Bushings • Track Rollers Water Pumps Plain and Antifriction Bearings

This selection guide is not intended to replace the specifications by the equipment builder.

LUBRICATION AND SEALS - *continued*

SEALS
SELECTING THE RIGHT SEAL

When selecting the proper seal design for any Timken bearing application, it is necessary to consider the type of lubricant, the operation environment, the speed of the application and general operating conditions.

Shaft finish

It is important to ensure that no spiral grooves result from machining of shaft surfaces since these will tend to draw lubricant out of, or contaminant into, the bearing cavity. Plunge grinding normally produces a satisfactory surface finish.

Grease lubrication - venting

Venting should be provided in the cavity between the two bearings when grease lubrication is used in conjunction with rubbing or non-rubbing seals. This will prevent an ingress of contamination past the seals, in the event of a pressure differential between the bearing cavity and atmosphere.

Vertical shaft closures - oil lubrication

Lubricating vertical shaft bearings is a difficult problem. Normally, grease, oil mist or oil-air lubrication is used because of the simplicity. However, some high speed and/or heavy load applications will use circulating oil. This requires a very good sealing system and a suction pump to remove the oil from the bottom bearing position.

NON-RUBBING SEALS
Metal stampings

Metal stamping closures are effective in clean applications. Where environmental conditions are dirty, stampings are used in combination with other closure elements to provide an effective labyrinth against the entry of foreign matter into the bearing chamber.

The stamping shown in Fig. A-32 is effective for applications that are grease-lubricated and operate in clean conditions. The design illustrated in Fig. A-33 uses stampings on both sides of the bearing to keep the grease in close proximity to the bearing. The flinger mounted at the outer side of the bearing adds a labyrinth effect.

Stampings should be designed to provide a clearance of 0.5 to 0.6 mm (0.020 to 0.025 in.) on diameters between rotating and stationary parts. A minimum axial clearance of 3 mm (0.125 in.) should be provided.
Fig. A-32
Metal stamping.
Fig. A-33
Metal stampings.

Machined flingers

Machined parts, along with other closure elements, can be used in place of stampings where closer clearances are desired. This results in a more efficient retention of lubricant and exclusion of foreign matter from the bearing housing. Examples are shown in Fig. A-34 and A-35.

An umbrella-shaped flinger is shown in Fig. A-35 combined with an annular groove closure. At high shaft speeds this combination effectively retains oil and keeps out dirt.
Fig. A-34
Machined flinger combined with annular grooves.
Fig. A-35
Machined umbrella flinger combined with annular grooves.

A

LUBRICATION AND SEALS - *continued*

Annular grooves

Annular groove closures are often used with grease lubrication in place of radial lip seals where considerable grit and dust are encountered. The closure usually has several grooves machined in the bore or on the outside diameter depending on the design. They become filled with grease, which tends to harden and provide a tight closure. When used with oil, the grooves tend to interrupt the capillary action which would otherwise draw oil out of the bearing cavity. Annular grooves with a machined labyrinth effectively protect a grease-lubricated bearing when the unit is required to operate in an extremely dirty environment (Fig. A-36). This type of closure is most effective when applied with close-running clearances and the maximum possible number of grooves. Suggested dimensions are shown in Fig. A-37.
Fig. A-36
Annular grooves combined
with machined labyrinth.
dimension "a"	3.20 - 4.80 0.125 - 0.190	
dimension "b"	4.00 - 4.80 0.160 - 0.190	
dimension "c"	0.5a	
diametral clearance	0.25 - 0.40 0.010 - 0.016	for diameters to 50 mm (2 in)
	1.3 max. 0.05 max.	for diameters over 50 mm (2 in)

Fig. A-37
Annular grooves. Suggested
dimensions (mm, in.).

RUBBING SEALS
Radial lip seals

Many types and styles of radial lip seals are commercially available to satisfy different sealing requirements. In clean environments, where the primary requirement is the retention of lubricant in the bearing housing, a single lip seal with the lip pointing inward is often used. Where the critical concern is exclusion of contaminants, the lip is usually pointed outwards (Fig. A-38).
Fig. A-38
Radial lip seals.

Lip seals are available with or without a spring-loaded lip. The spring maintains a constant pressure of the lip on the sealing surface, thereby providing a more efficient seal for a longer period of time. When environmental conditions require a seal to prevent contaminants from entering the bearing chamber as well as retaining the lubricant, a double or triple lip seal is often used. Additional flingers or shrouds should be used as primary seals where extremely dirty conditions are present so that the seal lip and sealing surface are protected to avoid rapid wear and premature seal damage (Fig. A-39).

Seal wear surfaces are normally required to have a surface finish in the order of 0.25-0.40 μm (10-15 μin.) R_a. For applications exposed to severe contamination, the seal wear surface should in general have a minimum surface hardness of Rockwell C-45. The seal supplier should be consulted for more specific guidance.
Fig. A-39
Lip seal plus machined labyrinth.

LUBRICATION AND SEALS - *continued*

"DUO FACE®-PLUS" seals

The "DUO FACE®-PLUS" seal (Fig. A-40) has double lips that seal in the housing bore and the ground surface of the outer race front face. This eliminates the need to machine a special seal surface. The "DUO FACE®-PLUS" seal has proven successful in many different types of grease-lubricated applications. The range of Timken bearings available with "DUO FACE®-PLUS" seals is listed in this book. Also, a brochure showing application examples is available on request.
Fig. A-40
DUO FACE® –PLUS seal.

Diaphragm seals

Diaphragm seals (Fig. A-41) are commercially available. The metallic lip is designed to be spring-loaded against the narrow face of the outer race. The type shown in Fig. A-41b has a second lip which seals against the housing.
Fig. A-41
Diaphragm seal.

Fig. A-41b
Diaphragm seal.

Mechanical face seals

These are often used in extremely dirty environments where rotational speeds are low. Fig. A-42 shows one of the proprietary types of mechanical face seals available. This type of seal generally needs to run in an oil bath. Designs are also available for high-speed and other special applications.

Fig. A-42
Mechanical face seal for low speeds and contaminated environment.

V-ring seals

V-ring seals can be used in conjunction with grease or oil lubrication. As rotational speeds increase, the lip tends to pull away from the sealing surface and act like a flinger. This seal may be used with either oil or grease lubrication (Fig A-43). Consult your V-ring seal supplier for application restrictions.
Fig. A-43
V-ring seals.

A

BALL BEARINGS WITH SHIELDS AND SEALS

Shields (D-Type)

Both K and W single-row radial types are available with one shield, designated by suffix D, or two shields, suffix DD. A shield on one side provides protection against the entrance of coarse dirt or chips and makes it possible to relubricate the bearing from the open side as shown (at right).

Double-shielded bearings are prelubricated with the correct amount of Timken suggested ball bearing grease and are designed for applications where relubrication is not required. Typical mountings are shown.

One Shield-Suffix D

Two Shields-Suffix DD
Labyrinth or Mechani-Seals (L-Type)

Bearings with Mechani-Seals are made in the non-filling slot type only and are available with a single seal, designated by suffix L, one seal and one shield, suffix LD, and two seals, suffix LL. These bearings have standard bores, outside diameters and outer ring widths, but the inner ring is wider than standard unshielded and shielded sizes. As illustrated, in the L and LD-Types, the inner rings are offset slightly on the side opposite the seal in order to permit clearance when the bearings are mounted in blind housings.

The Mechani-Seal was developed by Timken to provide a frictionless seal for effective grease retention and exclusion of foreign material. It consists of two "dished" steel plates. The inner member is fixed securely in the outer ring of the bearing and provides an ample grease chamber plus effective grease retention. The outer member is pressed on the outside diameter of the inner ring and rotates as a slinger to throw off contaminants. Close running clearances between the inner and outer members assure effective sealing under extremely severe conditions. This seal configuration is very effective under high speed, because it is virtually frictionless and utilizes slinger action. Mechani-Seal bearings are very popular in high-speed pneumatic tools, small electric motors, pumps, domestic appliances and similar high-speed applications. A typical mounting arrangement for the LL-Type is shown.

Wide-type radial bearings (W-LL-Type) with Mechani-Seals are designated by the prefix W and suffix LL for two seals. They are made in standard bores and outside diameters, but in widths the same as those of corresponding size double-row bearings. The extra width affords greater space for long-life factory-filtered grease and provides extra support on shafts and in housings so that locknuts and lockwashers are not needed on applications such as electric motors. A typical mounting is shown (at right).

Suffix LD

Two Mechani-Seals Suffix LL
W-LL-Type Typical Mounting

LUBRICATION AND SEALS - *continued*

Felt Seals (T-Type)

The felt seal consists of two metal plates fixed in the outer ring of the bearing that enclose a felt washer. This felt washer, which is saturated with oil before assembly in the bearing, contacts the ground outside diameter of the inner ring to provide sealing with minimum friction drag.

Bearings with felt seals are made only in the non-filling slot type and are available with one seal (designated by the suffix T), one seal and one shield (identified by suffix TD), and two seals (suffix TT). Bores and outside diameters of these bearings are the same as standard unshielded and shielded types, but overall widths are greater. As illustrated, in the T-and TD-types, the inner rings are offset slightly on the opposite side of the seal to permit clearance when the bearings are mounted in blind housings as illustrated.

Rubber Seals (P-Type)

Radial bearings with rubber seals having one or two seals are designated by the suffixes P and PP, respectively. With the exception of the extra-small sizes, they are dimensionally interchangeable with open-type and shielded bearings.

The P-Type design is a positive contact seal using a molded synthetic rubber. Firmly fixed to the outer ring, the seal flares outward and rides on the inner ring. The flare-out of the seal against the inner ring radius assures constant positive contact to provide an effective barrier against the entrance of contaminants or loss of lubricants.

Because they interchange dimensionally with standard single-row radial types, Timken® rubber seal bearings provide a convenient compact design.

Wide-type radial rubber seal bearings (W-PP Type) designated by prefix W and suffix PP for two seals are made with standard bores and outside diameters, but with widths the same as those as corresponding double-row bearings. This design also utilizes a molded seal.

The extra width offers a larger contact area for the shaft and housing and also provides additional space for displacement of grease under agitation.

These wide type rubber seal bearings are particularly well-suited for use by electric motor manufacturers where their advantages have helped simplify design. A typical example of motor design simplification is illustrated (right).

LUBRICATION AND SEALS - *continued*

### Rubber Seals (R-Type)

One of the most advanced sealing designs introduced by Timken is the R-Type rubber seal bearing. This is a positive contact seal of three-piece construction, utilizing a synthetic rubber seal retained by two steel caps. The seal flares outward and rides or wipes on the ground land of the inner ring. In this design, the rubber sealing element is completely protected by a closely fitting outer cap or shroud, which nests tightly against the seal member following its flared-out shape at the inner ring of the outside diameter. The innermost member is crimped into a groove in the outer ring and encapsulates the seal and outside shroud. Providing firm seal contact, the back-up plate of the seal assembly has a close clearance with the outside diameter of the inner ring, preventing the seal from being pushed inward.

Laboratory tests have clearly established the superior performance of the shroud-type R-Seal. With improved lubricant retention and greater protection against contaminants, the shroud design guards the rubber seal against abrasive damage by dirt and fiber wrap, which may be prevalent in agriculture and textile applications. This seal construction also is available in standard and heavy series wide inner ring bearings.

Tri-Ply Seals

Tri-Ply Shroud Seal ball bearings are designed for bearing applications involving exceptionally severe contamination or abrasion environments. They are produced in many types and sizes, both in the radial and wide inner ring designs.

Each Tri-Ply seal consists of a triple-lip nitrile seal molded to a heavy metal shroud cap. All three seal lips have heavy flare-out contact with the inner ring outside diameter and provide exceptionally effective protection against the loss of lubricant and the entrance of wet or abrasive contaminants. The shroud cap, which nests closely with the outside seal lip, helps protect the rubber seal members from wrap and abrasion.

A feature of these bearings is the balanced design, consisting of deep raceways, large ball size, and extra-wide or heavy inner rings. The use of Tri-Ply bearings simplifies housing designs, and their extra inner ring width provides greater support on the shaft. These bearings are widely used on conveyors and farm machinery such as disc harrows, hillers, tomato harvesters, cotton harvesters, etc.

SPEED, HEAT AND TORQUE

SPEED RATINGS
RADIAL BALL BEARINGS

There is no precise method for determining the maximum speed at which a ball bearing may operate. Bearing characteristics and features of surrounding parts, shafts, housing and other component as well as basic service conditions are all variables dependent upon each other for continued satisfactory high-speed performance.

The safe operating speed of a bearing is often limited by the temperature within the bearing, which, in turn, is dependent upon the temperature surrounding the application, accuracy of bearings, shafts, housings, auxiliary parts, etc., and the type and amount of lubricant.

Radial bearings with proper internal refinements will operate at high speeds for long periods if properly installed and lubricated. Tolerance grade, cage design, and lubricant are bearing characteristics which affect speed limitations.

Bearings with ABEC 1 tolerances are generally satisfactory for normal speeds with grease or oil lubrication.

Ball bearings with ABEC 5 tolerances or better and ring-piloted composition cages lubricated with an efficient, non-churning, cooling oil-mist system have exceptional high-speed ability.

In the case of duplex mountings, as frequently used in a high-speed machine tool spindles, bearing preload and contact angle affect the permissible speeds.

The values in the accompanying table may be used as a general guide for determining the safe maximum speed of standard types of Timken ball bearings. To obtain the speed value for any bearing size with inner ring rotating, multiply the pitch diameter in millimeters (or, in the case of extra-small inch dimension bearings, the nearest millimeter equivalent) by the speed in revolutions per minute. Refer to page A164 for the most suitable bearing type, cage style, tolerance guide and type of lubrication.

For outer ring rotation of ball bearings, multiply the speed value (pitch or mean dia. in. mm x RPM of the outer ring) by the following factors before referring to the table of speed values.

BALL BEARING SERIES FACTOR	
Extra-small (30 and S) and extra-light (9100 and M9300)	1.3
Light (200, 5200 and 7200)	1.5
Medium (300, 5300 and 7300)	1.7

Although the speed values shown in the tables on the following page are based on many years of research and accumulated data, numerous application of Timken bearings are successfully operating with speed values far in excess of those tabulated. Such applications require particular consideration of proper tolerance grade, lubrication, the effect of centrifugal force on rolling elements and other factors. For further information consult your Timken representative.

Conversely, under certain application conditions of load, temperature, contamination, etc., limiting speeds may be less than the figures shown. These values do not apply to certain special bearings, such as radial Tri-Ply series, square or hex bore bearings.

The speed capability of a bearing in any application is subject to a number of factors including:
- Temperature.
- Bearing setting or clearance.
- Lubrication.
- Bearing design.

The relative importance of each of these factors depends on the nature of the application. The effect of each factor is not isolated – each contributes in varying degrees, depending on the application and overall speed capability of the design.

An understanding of how each of these factors affects performance as speeds change is required to achieve the speed capabilities inherent in a bearing.

SPHERICAL AND CYLINDRICAL ROLLER BEARINGS

For Timken cylindrical and spherical roller bearings, the thermal speed ratings are listed in the bearing tables. These values have been determined by balancing the heat generated within the bearing with the heat dissipated from the bearing. In calculating these numbers, the following assumptions have been made:
- The radial load is five percent of the static load rating.
- For oil, it is assumed to be in a bath with the fill to the middle of the lowest rolling element. For grease it is assumed a 30 percent bearing cavity fill.
- The oil viscosity is assumed to be 12 cSt (ISO VG32) operated at 70° C, (158° F) and the grease base oil viscosity is assumed to be 22 cSt operated at 70° C (158° F). The bearing and its components are at 70° C and the bearing environment is at 20° C (68° F).
- The housing and shaft are steel or cast iron.
- The bearing rotational axis is horizontal.
- The outer ring is stationary and the inner ring is rotating.
- The bearing radial internal clearance complies with class normal and standard fits are used.
- The bearing does not contain seals.
- The bearing does not experience misalignment or axial load.

The thermal speed ratings are for reference only and can be considerably lower or higher depending on your application. Consult your Timken representative for more accurate information regarding a bearing's speed limitations in your application.

$$* \frac{\text{Bore + O.D.}}{2}$$

[1] For oil bath lubrication, oil level should be maintained covering between ⅓ to ½ up from the bottom of the lowest ball.

Note: Single or double normal contact (P or PP) sealed bearings should not exceed 300,000 PDN. Consult your Timken representative for limiting speed of RR or Tri-Ply sealed bearings.

SPEED, HEAT AND TORQUE - *continued*

TAPERED ROLLER BEARINGS

The usual measure of the speed of a tapered roller bearing is the circumferential velocity at the midpoint of the inner race large end rib (Fig. A-44). This may be calculated as:
Rib speed:

$$V_r = \frac{\pi D_m n}{60000} \ \text{(m/s)}$$

$$= \frac{\pi D_m n}{12} \ \text{(ft/min)}$$

where:

|			
D_m	=	Mean inner race large rib diameter	mm, in.
n	=	Bearing speed	rev/min

Fig. A-44
Cone rib diameter. The inner race rib diameter may be scaled from a print.

The mean large rib diameter at the midpoint of the roller end contact can be scaled from a drawing of the bearing, if available, or this diameter can be determined by consulting your Timken representative. The inner cone mean large rib diameter can be approximated by taking 99 percent of larger rib O.D.

DN values (the product of the inner race bore in mm and the speed in rev/min) are often used as a measure of bearing speed by other bearing manufacturers. There is no direct relationship between the rib speed of a tapered roller bearing and DN value because of the wide variation in bearing cross sectional thickness. However, for rough approximation, one meter per second rib speed is about equal to 16,000 DN for average section bearings. One foot per minute is equal to approximately 80 DN.

SPEED CAPABILITY GUIDELINES FOR VARIOUS TYPES OF LUBRICATION SYSTEMS
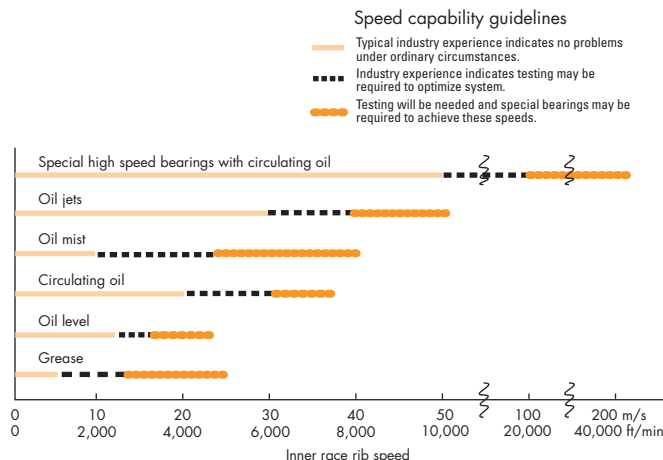

Fig. A-45

Fig. A-45 is a summary of guidelines relating to speed and temperature based on customer experience, customer tests and research conducted by The Timken Company. Consult your Timken representative with questions regarding high-speed capability.

A

OPERATING TEMPERATURES

TEMPERATURE LIMITATIONS

Bearing equilibrium temperature is not simply a question of speed. It is also dependent on the heat generation rate of all contributing heat sources, nature of the heat flow between sources, and heat dissipation rate of the system. Seals, gears, clutches, and oil supply temperature affect bearing operating temperature.

Heat dissipation rate is governed by such factors as type of lubrication system, materials and masses of the shaft and housing and intimacy of contact with the bearing, and surface area and character of the fluid both inside and outside the housing.

Temperature of the outer surface of the housing is not an accurate indication of bearing temperature. The inner ring temperature is often greater than the outer ring temperature and both are usually greater than the outer surface of the housing. There are temperature gradients within the bearing with the temperature of the internal parts usually being greater than the outer surfaces. Although the temperature of the outer ring O.D. or the inner ring I.D., or the oil outlet is often used as an indicator of bearing temperature, it should be recognized that these are generally not the highest bearing temperatures.

During transient conditions, such as at startup, bearing temperatures will often peak and then reduce to a lower level. This is due to the thermal changes taking place between the bearing, shaft and housing causing variations in setting and internal loading. Also, a new bearing will usually generate more heat until it runs in.

The allowable operating temperature depends on:
- Equipment requirements
- Lubrication limitations
- Bearing material limitations
- Reliability requirements

Each factor is an area of increasing concern as operating temperatures rise.

The equipment designer must decide how operating temperature will affect the performance of the equipment being designed. Precision machine tools, for example, can be very sensitive to thermal expansions. In many cases it is important that the temperature rise over ambient be minimized and held to 20 to 25° C (36 to 45° F) for some precision spindles.

Most industrial equipment can operate satisfactorily with considerably higher temperature rises. Thermal ratings on gear drives, for example, are based on 93° C (200° F).

Some equipment such as plastic calendars and gas turbine engines operate continuously at temperatures well above 100° C (212° F).

Standard bearing steels cannot maintain the desired minimum hot hardness of 58 HRC much above 135° C (275° F).

Standard Timken spherical roller bearings are dimensionally stabilized up to 200° C. Upon request, the bearings can be ordered with dimensional stabilization up to 250° C (S2 suffix) or 300° C (S3 suffix). Consult your Timken representative for availability in specific part numbers.

Standard Timken cylindrical roller bearings are dimensionally stabilized up to 150° C. Upon request, the bearings can be ordered with dimensional stabilization up to 200° C (S1 suffix), 250° C (S2 suffix) or 300° C (S3 suffix).

Dimensional stability of Timken ball bearings is achieved by tempering the hardened steel until any further growth by transformation of austenite to martensite is balanced by shrinkage from tempering martensite. This balance is never perfect, and some size change will always occur, the amount depending upon the operating time and temperature of the bearings and the composition of and heat treatment of the steel. The ABMA definition for stabilized rings and balls permits a change of less than .0001 inch per inch after exposure to a temperature of 300° F for 2,500 hours. Rings and balls used at elevated temperatures are defined as stable by ABMA where there is a size change of less than .00015 inch per inch after 1,500 hours exposure at temperatures of 450°, 600° and 800° F.

Above this, special high-temperature steels are used by Timken.

Timken CBS 600™ steel should be considered for temperatures between 150 to 230° C (300 to 450° F) and Timken CBS 1000M™ steel should be used for temperatures above 230° C (450° F) . Also, CBS 600 and CBS 1000M have increased resistance to scoring - important in very high-speed applications. Consult your Timken representative for availability of S1, S2, S3 suffixes or high-temperature steels in specific part numbers and applications.

Although bearings can operate satisfactorily at higher temperatures, an upper temperature limit of 80 to 95° C (176 to 203° F) is usually more practical for small, high volume equipment where prototype testing is possible. Higher operating temperatures increase the risk of damage from some unforeseen transient condition. If prototype testing is not practical, an upper design limit of 80° C (176° F) is appropriate unless prior experience on similar equipment suggests otherwise.

History on some machines operating at higher temperatures, such as high-speed rolling mills, offers good background data for establishing limits on new similar machines.

Obviously none of the above examples of equipment, lubricant or bearing materials limitations are single point limitations but rather areas of gradually increasing concern. It is the responsibility of the equipment designer to weigh all relevant factors and make the final determination of what operating temperature is satisfactory for his particular machine.

Suggested materials for use in rings, balls and rollers at various operating temperatures are listed together with data on chemical composition, hardness and dimensional stability. A temperature of 427° C (800° F) is generally the top limit for successful bearing operation using steels. Above 427° C (800° F), or below where lubricant is not permitted, cast or wrought cobalt alloys are generally used. Although chosen primarily for their good retention of physical properties, they also possess good oxidation resistance at elevated temperatures.

Suggested materials for cages, shields, and seals are tabulated on page A168 with their temperature capabilities.

Other Considerations

Until now, temperature limitation has been discussed in reference to metallurgical considerations. However, installations which operate at high temperatures for extended periods may lose the quality of shaft and housing fits. Carefully machined and heat-treated shafts and housings will minimize trouble from this source. In some applications the internal clearance of bearings may be partially absorbed. For example, during the first few seconds of rotation a massive housing may keep the outer race cooler than the inner race and rolling elements even if the housing is already at some elevated temperature and, also, during heat soakback when rotation stops heat may flow back to the bearing along the shaft. If, while stationary, the effects of heat soakback more than removes the radial internal clearance, radial brinell of the races may occur and the bearing will be rough during subsequent rotation. Bearings with extra internal looseness may be required to compensate for the above conditions.

HEAT GENERATION AND DISSIPATION

One of the major benefits of oil-lubricated systems is that the heat generated by the bearings is carried away by the circulating oil and dissipated through the system.

Heat generation

Under normal operating conditions, most of the torque and heat generated by the bearing is due to the elastohydrodynamic losses at the roller/race contacts.

The following equation is used to calculate the heat generated by the bearing:

$$Q_{gen} = k_4 n\, M$$
$$M = k_1 G_1\, (n\mu)^{0.62}\, (P_{eq})^{0.3}$$

where:

Q_{gen} = generated heat (W or Btu/min)
M = running torque N.m or lbf-in.
n = rotational speed (RPM)
G_1 = geometry factor from bearing data tables
μ = viscosity at operating temperature (cP)
P_{eq} = equivalent dynamic load (N or lbf)
k_1 = bearing torque constant
    = 2.56×10^{-6} for M in N-m
    = 3.54×10^{-5} for M in lbf-in.

Heat dissipation

The heat dissipation rate of a bearing system is affected by many factors. The modes of heat transfer need to be considered. Major heat transfer modes in most systems are conduction through the housing walls, convection at the inside and outside surfaces of the housing, and convection by the circulating lubricant. In many applications, overall heat dissipation can be divided into two categories: Heat removed by circulating oil and heat removed through the housing.

Heat dissipation by circulating oil

Heat dissipated by a circulating oil system is:

$$Q_{oil} = k_5 f\quad (\theta_o - \theta_i)$$

If a circulating lubricant other than petroleum oil is used, the heat carried away by that lubricant will be:

$$Q_{oil} = k_6\, C_p \rho f\, (\theta_o - \theta_i)$$

The following factors apply to the heat generation and dissipation equations listed on this page.

k_4 Dimensional factor to calculate heat generation rate
   k_4 = 0.105 for Q_{gen} in W when M in N-m
      = 6.73×10^{-4} for Q_{gen} in Btu/min when M in lbf-in.

k_5 Dimensional factor to calculate heat carried away by a petroleum oil
   k_5 = 28 for Q_{oil} in W when f in L/min and θ in °C
      = 0.42 for Q_{oil} in Btu/min when f in U.S. pt/min and θ in °F

k_6 Dimensional factor to calculate heat carried away by a circulating fluid
   k_6 = 1.67×10^{-5} for Q_{oil} in W
      = 1.67×10^{-2} for Q_{oil} in Btu/min

Q_{oil}	Heat dissipation rate of circulating oil	W, Btu/min
θ_i	Oil inlet temperature	°C, °F
θ_o	Oil outlet temperature	°C, °F
C_p	Specific heat of lubricant	J/(kg x °C), Btu/(lb x °F)
f	Lubricant flow rate	L/min, U.S. pt/min
ρ	Lubricant density	kg/m³, lb/ft³

SPEED, HEAT AND TORQUE - *continued*

These tables provide standard operating temperatures for common bearing component materials. They should be used for reference purposes only. Other bearing component materials are available on request. Contact your Timken representative for further information.

OPERATING TEMPERATURES FOR BEARING COMPONENT MATERIALS

				Operating Temperature												
Material	**Approximate Chemical Analysis-%**	**Temp. °F**	**Hardness HRC**	**-100° F -73° C**	**-65° F**	**0° F -17° C**	**100° F 38° C**	**200° F 93° C**	**250° F**	**300° F 149° C**	**400° F 204° C**	**500° F 260° C**	**600° F 316° C**	**700° F 371° C**	**800° F 427° C**
Low alloy carbon-chromium bearing steels. 52100 and others per ASTM A295	1C 0.5-1.5Cr 0.35Mn	70	60			STANDARD DIMENSIONAL STABILIZATION <0.0001 in/in dimensional change in 2,500 hours at 212° F. Good oxidation resistance.								
Low alloy carbon-chromium bearing steels. 52100 and others per ASTM A295	1C 0.5-1.5Cr 0.35Mn	70 350 450	58 56 54			Heat stabilized per FS136 <.0001 in./in dimensional change in 2,500 hours at 300° F When given a stabilizing heat treatment, A295 steel is suitable for many applications in the 350-450° F range; however, it is not as stable dimensionally as it is at temperatures below 350° F. If utmost stability is required, use materials in the 600° F group below.								
Deep hardening steels for heavy sections per ASTM A485	1C 1-1.8Cr 1-1.5 Mn .06Si	70 450 600	58 55 52			As heat treated and tempered, it is stabilized, <.0001 in/in dimensional change in 2500 HR at 300 ° F (149° C).								
Carburizing steels per ASTM A534 (a) low alloy 4118 (b) 8620 (c) high nickel 3310	.2C, .5Cr, .80Mn, .12Mo .2C, .5Cr, .80 Mn, .20 Mo, .55Ni .10C, 1.60Cr, .50Mn, 3.50Ni	70	58			4118,8620 steel frequently used to achieve extra ductility in inner rings for locking device bearings. 3310 and others used for extra thick section rings.								
Corrosion Resistant 440C stainless steel per ASTM A756	1C 18Cr	70	58			Excellent corrosion resistance.								
Corrosion Resistant 440C stainless steel per ASTM A756	1C 18Cr	70 450 600	58 55 52		As heat stabilized for maximum hardness at high temperatures (FS238). Good oxidation resistance at higher temperatures. Note load capacity drops off more rapidly at higher temperatures than M50 shown below, which should be considered if loads are high. <.0001 in/in dimensional change in 1,200 hours.									
M-50 Medium High Speed	4 Cr. 4 Mo 1V 0.8C	70 450 600	60 59 57		Recommended where stable high hardness at elevated temperature is required. <.0001 in/in dimensional change in 1,200 hours at 600° F.									

Dimensional stability data shown above is the permanent metallurgical growth and/or shrinkage only. Thermal expansion effects are not included. Bearings have been made of special material for operation at temperatures above 800° F. Consult your Timken representative regarding the application.

Note: ASTM A295 bearing steels are suitable for many applications up to 250° F but are not as dimensionally stable as they are at temperatures below 212° F.

SPEED, HEAT AND TORQUE - *continued*

TORQUE
TAPERED ROLLER BEARINGS

Running torque-M

The rotational resistance of a rolling bearing is dependent on load, speed, lubrication conditions and bearing internal characteristics.

The following formulas yield approximations to values of bearing running torque. The formulas apply to bearings lubricated by oil. For bearings lubricated by grease or oil mist, torque is usually lower, although for grease lubrication this depends on amount and consistency of the grease. The formulas also assume the bearing running torque has stabilized after an initial period referred to as "running-in."

Single-row tapered roller bearing
Design (external thrust, F_{ae}, onto bearing A)

Thrust condition	Net bearing thrust load	
$\dfrac{0.47\,F_{rA}}{K_A} \leq \dfrac{0.47\,F_{rB}}{K_B} + F_{ae}$	$F_{aA} = \dfrac{0.47\,F_{rB}}{K_B} + F_{ae}$ $F_{aB} = \dfrac{0.47\,F_{rB}}{K_B}$	$M = k_1\,G_1\,(n\mu)^{0.62}\left(\dfrac{f_1\,F_r}{K}\right)^{0.3}$
$\dfrac{0.47\,F_{rA}}{K_A} > \dfrac{0.47\,F_{rB}}{K_B} + F_{ae}$	$F_{aA} = \dfrac{0.47\,F_{rA}}{K_A}$ $F_{aB} = \dfrac{0.47\,F_{rA}}{K_A} - F_{ae}$	$n_{min} = \dfrac{k_2}{G_2\mu}\left(\dfrac{f_2\,F_r}{K}\right)^{2/3}$

NOTE: The torque equations will be underestimated if operating speed, n, is less than n_{min}.
For values of f_1 and f_2, refer to figure A-46 on page A171.

SPEED, HEAT AND TORQUE - *continued*

Double-row tapered roller bearing
Design (external thrust, F_{ae}, onto bearing A)

Fixed position

Load condition	Radial load on each row F_r	
$F_{ae} > \dfrac{0.47\,F_{rAB}}{K_A}$	Bearing B is unloaded $F_{rA} = F_{rAB}$ $F_{aA} = F_{ae}$	$M = k_1\,G_1\,(n\mu)^{0.62} \left(\dfrac{f_1\,F_{rAB}}{K} \right)^{0.3}$ $n_{min} = \dfrac{k_2}{G_2\mu} \left(\dfrac{f_2\,F_{rAB}}{K} \right)^{2/3}$
$F_{ae} \leq \dfrac{0.47\,F_{rAB}}{K_A}$	$F_{rA} = \dfrac{F_{rAB}}{2} + 1.06\,K\,F_{ae}$ $F_{rB} = \dfrac{F_{rAB}}{2} - 1.06\,K\,F_{ae}$	$M = k_1\,G_1\,(n\mu)^{0.62} \left(\dfrac{0.060}{K} \right)^{0.3} (F_{rA}^{0.3} + F_{rB}^{0.3})$ $n_{minA} = \dfrac{k_2}{G_2\mu} \left(\dfrac{1.78 F_{rA}}{K} \right)^{2/3}$; $n_{minB} = \dfrac{k_2}{G_2\mu} \left(\dfrac{1.78 F_{rB}}{K} \right)^{2/3}$

Floating position

$M = 2\,k_1\,G_1\,(n\mu)^{0.62} \left(\dfrac{0.030\,F_{rC}}{K} \right)^{0.3}$

$n_{min} = \dfrac{k_2}{G_2\mu} \left(\dfrac{0.890\,F_r}{K} \right)^{2/3}$
Floating bearing

NOTE: The torque equations will be underestimated if operating speed, n, is less than n_{min}.
For values of f_1 and f_2, refer to figure A-46 on page A171.

M = running torque, N.m (lbf-in.)
F_r = radial load, N (lbf)
G_1 = geometry factor from bearing data tables
G_2 = geometry factor from bearing data tables
K = K-factor
n = speed of rotation, rev/min
k_1 = 2.56×10^{-6} (metric) or 3.54×10^{-5} (inch)
k_2 = 625 (metric) or 1700 (inch)
μ = lubricant dynamic viscosity at operating temperature centipoise
     For grease, use the base oil viscosity.
f_1 = combined load factor, see chart on A171
f_2 = combined load factor, see chart on A171

SPEED, HEAT AND TORQUE - *continued*
Fig. A-46

DETERMINATION OF COMBINED LOAD FACTORS f_1 AND f_2

Load condition	f_1 and f_2
$KF_a/F_r > 2.0$	$f_1 = KF_a/F_r$ $f_2 = f_1 + 0.8$
$0.47 \leq KF_a/F_r \leq 2.0$	use graph above
$KF_a/F_r < 0.47$	$f_1 = 0.06$ $f_2 = 1.78$

SPEED, HEAT AND TORQUE - *continued*
Viscosities in mPa.s (centipoise, cP) for ISO/ASTM industrial fluid lubricant grade designations. Assumes: Viscosity Index 90; Specific Gravity 0.875 at 40° C.

SPEED, HEAT AND TORQUE - *continued*

NEEDLE ROLLER BEARINGS

Empirical torque equations for radial and thrust needle bearings were developed by Timken:

$$M = d_m (4.5 \times 10^{-7} v^{0.3} n^{0.6} + 0.12 F_r^{0.4})$$

Testing also showed that full complement radial needle roller bearings operate at 1.5 to 2 times the torque determined for caged radial needle roller bearings. Similarly, the running torque of thrust needle roller bearings is given:

$$M = 4.5 \times 10^{-7} v^{0.3} n^{0.6} d_m + 0.016 F_a l$$

In both equations, the mean diameter d_m is the average of the bore and O.D. Of the bearings, while the length (l) in the thrust bearing torque equation can be approximated using the bearing's radial section (e.g., $l = \frac{1}{2} [E_a - E_b]$). Finally, note that the viscosity is in units of centistokes, while that for tapered roller bearings was in centipoise. A typical conversion factor for mineral oil is 1 cSt = 0.875 cp.

Both of the aforementioned equations were determined for circulating oil lubrication systems. For grease lubrication, the viscosity of the base oil should be used to estimate the running torque.

CYLINDRICAL AND SPHERICAL ROLLER AND BALL BEARINGS

The torque equations for cylindrical and spherical roller bearings are given as follows, where the coefficients are based on series and found in the following table:

$$M = \begin{cases} f_1 F_\beta d_m + 10^{-7} f_0 (v \cdot n)^{2/3} d_m^3 & \text{if} \ (v \cdot n) \geq 2000 \\ f_1 F_\beta d_m + 160 \times 10^{-7} f_0 d_m^3 & \text{if} \ (v \cdot n) < 2000 \end{cases}$$

Again, note that the viscosity is in units of centistokes. The load term (F_β) is dependent on bearing type as follows:

Radial Ball:
$$F_\beta = \max \begin{pmatrix} 0.9 F_a \cot \alpha - 0.1 F_r \\ \text{or} \\ F_r \end{pmatrix}$$

Radial Cylindrical and Spherical Roller:
$$F_\beta = \max \begin{pmatrix} 0.8 F_a \cot \alpha \\ \text{or} \\ F_r \end{pmatrix}$$

Thrust Ball and Cylindrical and Spherical Roller:
$$F_\beta = F_a$$
